ISCHEMIC HEART DISEASE

Although atherosclerosis of the coronary arteries is the most common mechanism responsible for myocardial ischemia, other less common mechanisms can also cause ischemia. These include:

- Coronary emboli
- Coronary spasm (incl. toxic) Can be spontaneous or toxic induced (i.e. cocaine)
- Complications of connective tissue disorders

Natural History of Atherosclerosis

Know the risk factors of patients.

Atherosclerosis Risk Factors:

Genetics

Cigarette smoking

Hypertension

Diabetes mellitus

Dyslipidemias

Inflammation

MAJOR SYNDROMES

ANGINA PECTORIS

STABLE ANGINA

On exertion patient will have chest pain but at night or with nitrates it will go away. Usually due to a critical stenosis, which becomes apparent when the heart needs greater blood flow.

May occur during sleep and does not respond to angina.

UNSTABLE ANGINA

MYOCARDIAL INFARCT

SUDDEN CARDIAC DEATH

ISCHEMIC CARDIOMYOPATHY

When the heart doesn't get good blood and oxygen, the heart doesn't function properly. You will see both functional change and change in heart structure which can affect the mitral valve. If myocardium is ischemic, you can also get mitral regurgitation.

PREVALENCE OF ISCHEMIC HEART DISEASE

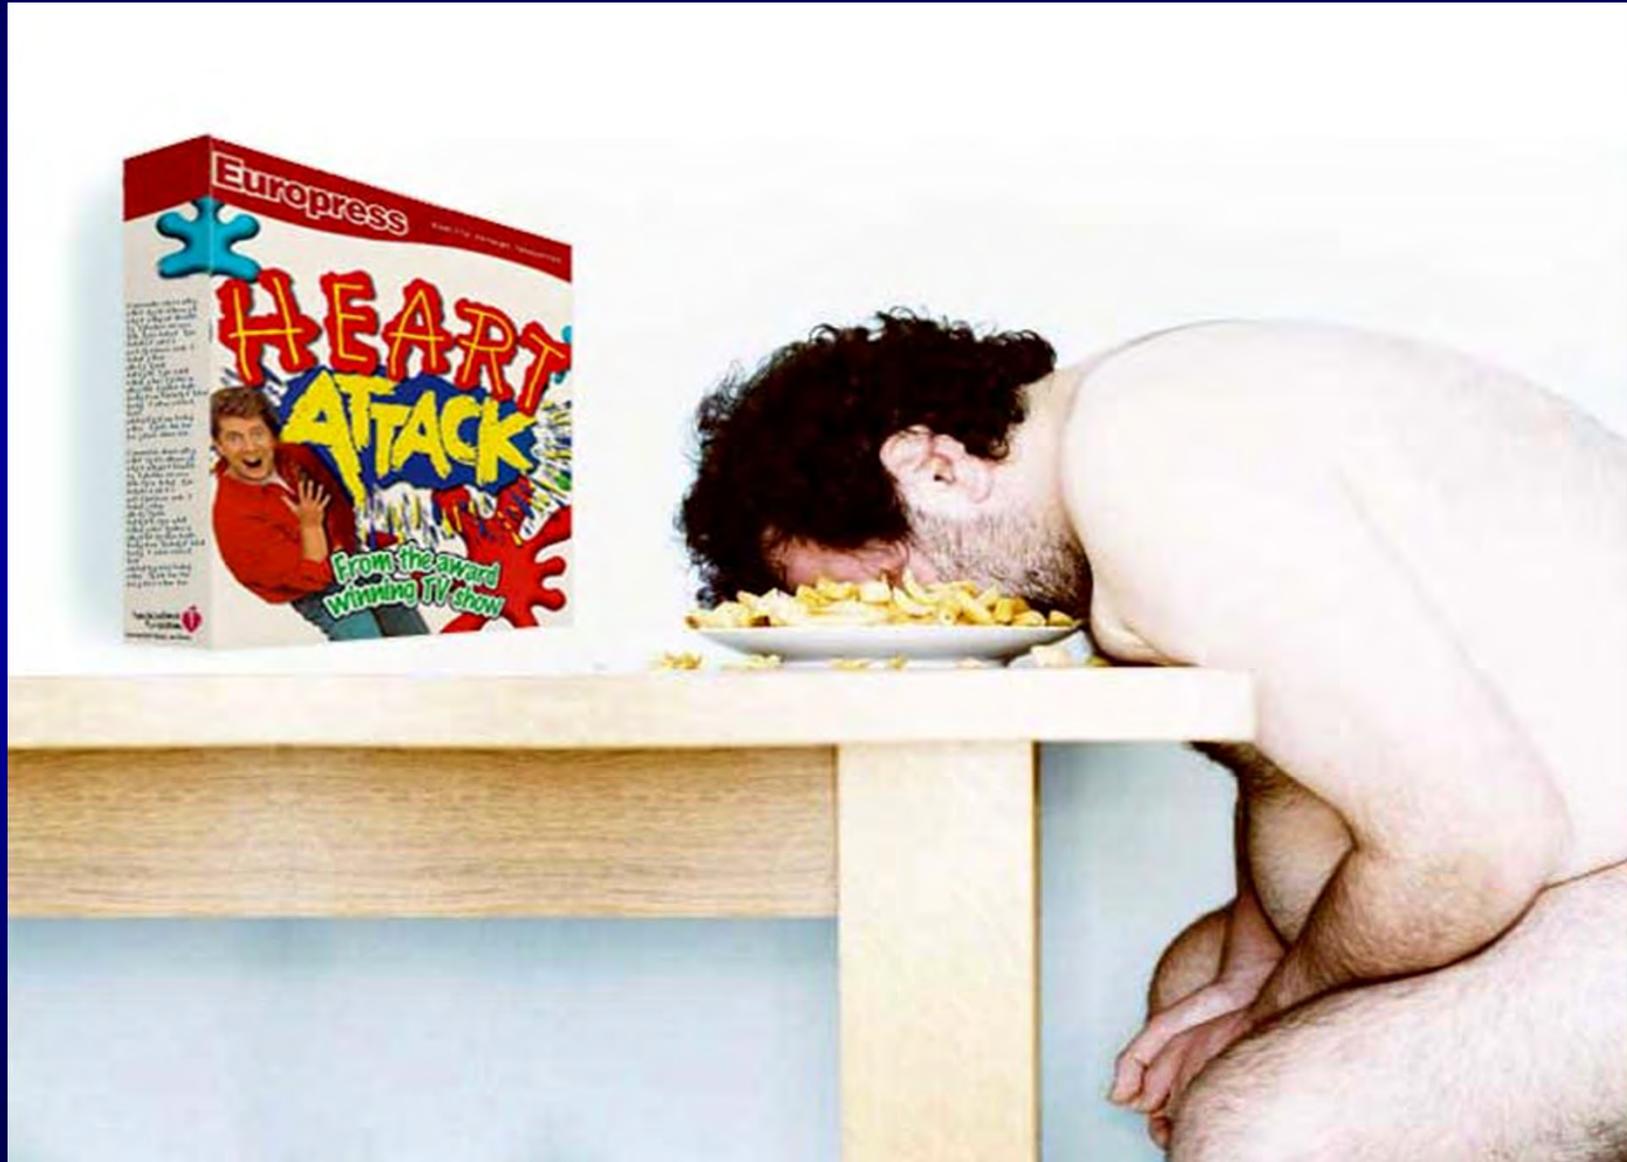

13.5 million Americans (7% of adult population) have symptomatic IHD evidenced by:

Angina Pectoris (50%)

Previous MI (>50%) ... or both

>500,000 deaths/year (one-third of all U.S. deaths) one-third are premature, i.e. before age 75

Sudden Cardiac Death

Definition:

- **Natural Unexpected Death Secondary to Cardiac Causes With Rapid Loss of Consciousness**

Patient has some cardiac issue that leads to sudden cessation of cardiac function. Arrhythmia, MI, aneurysm

- **Risk factors and Existing Disease may be previously documented**

Interestingly, you can survive sudden cardiac death. If you are resuscitated or defibrillated, you have survived a sudden cardiac death event. However, most patients will die within 24 hours.

Atherosclerosis: CAD

- 50% of deaths from CAD are SCD
- **50 – 60% of SCD is the first Clinical manifestation of CAD**
- 10% of patients with CAD first presentation is SCD

SCD: Incidence

- 300,000- 350,000 annually in the U.S.
- 0.1-0.2% per year for > 35 years old
- **Age peaks:**
 - Birth to 6 months (SIDS, congenital)
 - 45 -75 years old
 - Teens - 30 yo: incidence is only .001%
- **Gender:**
 - Male: Female **3-7:1 prior to menopause**

Sudden Infant Death Syndrome

Etiology: Age Dependent

- > 30 years
 - **Atherosclerosis (ischemia) ~ 2/3 of SCD**
 - **Cardiomyopathies**
 - **LVH, HOCM, ARVD, DCM**
 - **Myocarditis / Endocarditis / Infectious**
 - **Infiltrative / Storage Disorders**
 - **Fabry's, Hemochromatosis, Sarcoid, Amyloid, Desminopathy**
 - **Vascular Disease / Valvular Disease**
 - **Aneurysms, Dissections, Cong. Coronary Anomalies**
 - **Conduction System/Channelopathies**
- **CHF – may be feature of many prior to “sudden death”**

Hypertrophic cardiomyopathy

Arhythmogenic ventricular dysplasia

dilated cardiomyopathy

Can be structural or genetic

SUDDEN CARDIAC DEATH

ELECTROPHYSIOLOGY: Ventricular Fibrillation, Asystole, PEA

If there is asystole, generally you are not going to resuscitate that patient.

ANATOMIC FINDINGS:

Mostly discovered during autopsy

- Acute Coronary Plaque Rupture or Thrombosis (minority of cases)
- Acute or Organizing (clinically silent?) MI (minority of cases)
- No acute lesion but >60% stenosis of a coronary artery, often LAD (1° VF)

Patient won't know that they have had an MI.

ISCHEMIC HEART DISEASE

The underlying cause of ischemic heart disease is usually atherosclerosis of the coronary arteries

The most common cause of acute coronary syndromes (unstable angina or acute myocardial infarction) is a sudden increase in luminal narrowing due to thrombosis and/or plaque rupture.

Plaque Rupture and Thrombosis

Acute Arterial Occlusion

Vulnerability to **Plaque Rupture**

Large Atheromatous Core

Calcification with Erosion

Thin Fibrous Cap/Increased Cap Tension

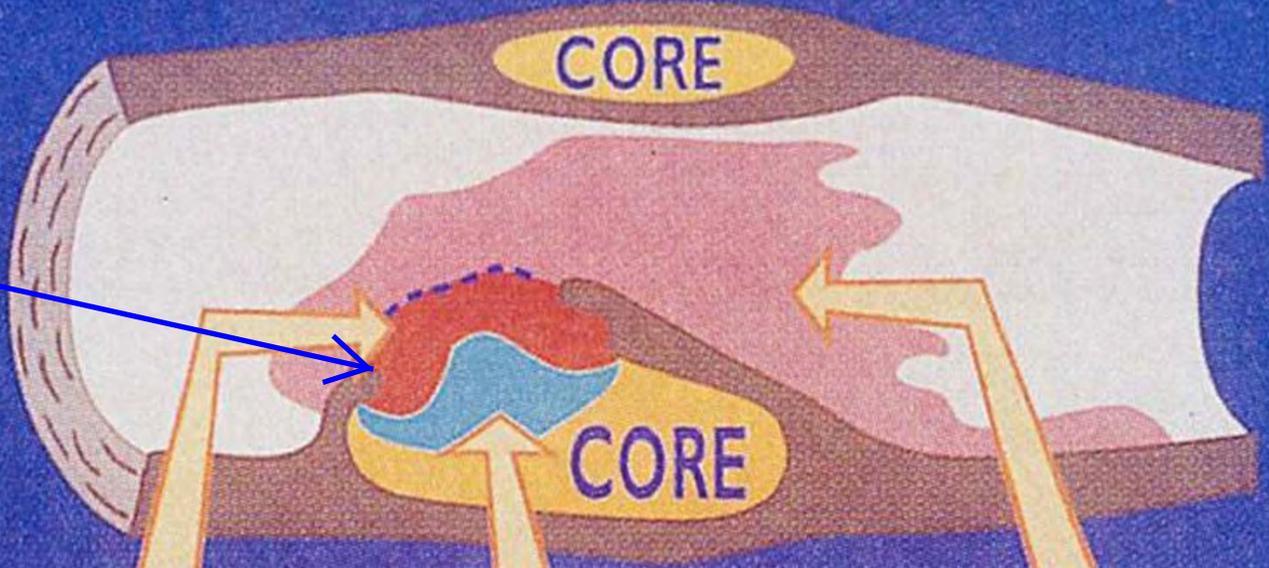

Inflammation, Foam Cells in Fibrous Cap

Matrix Metalloproteases

Cap Fatigue

If a patient has vulnerable plaques, its not usually the severity but rather the fact that they have one or more of the conditions on this list, which leads to higher risk of rupture. Can occur at 20-40% stenosis.

Propagation into lumen causes stenosis.

**TRANSITIONAL
ZONE THROMBUS**

**FIBRIN
PLATELETS
ON SURFACE**

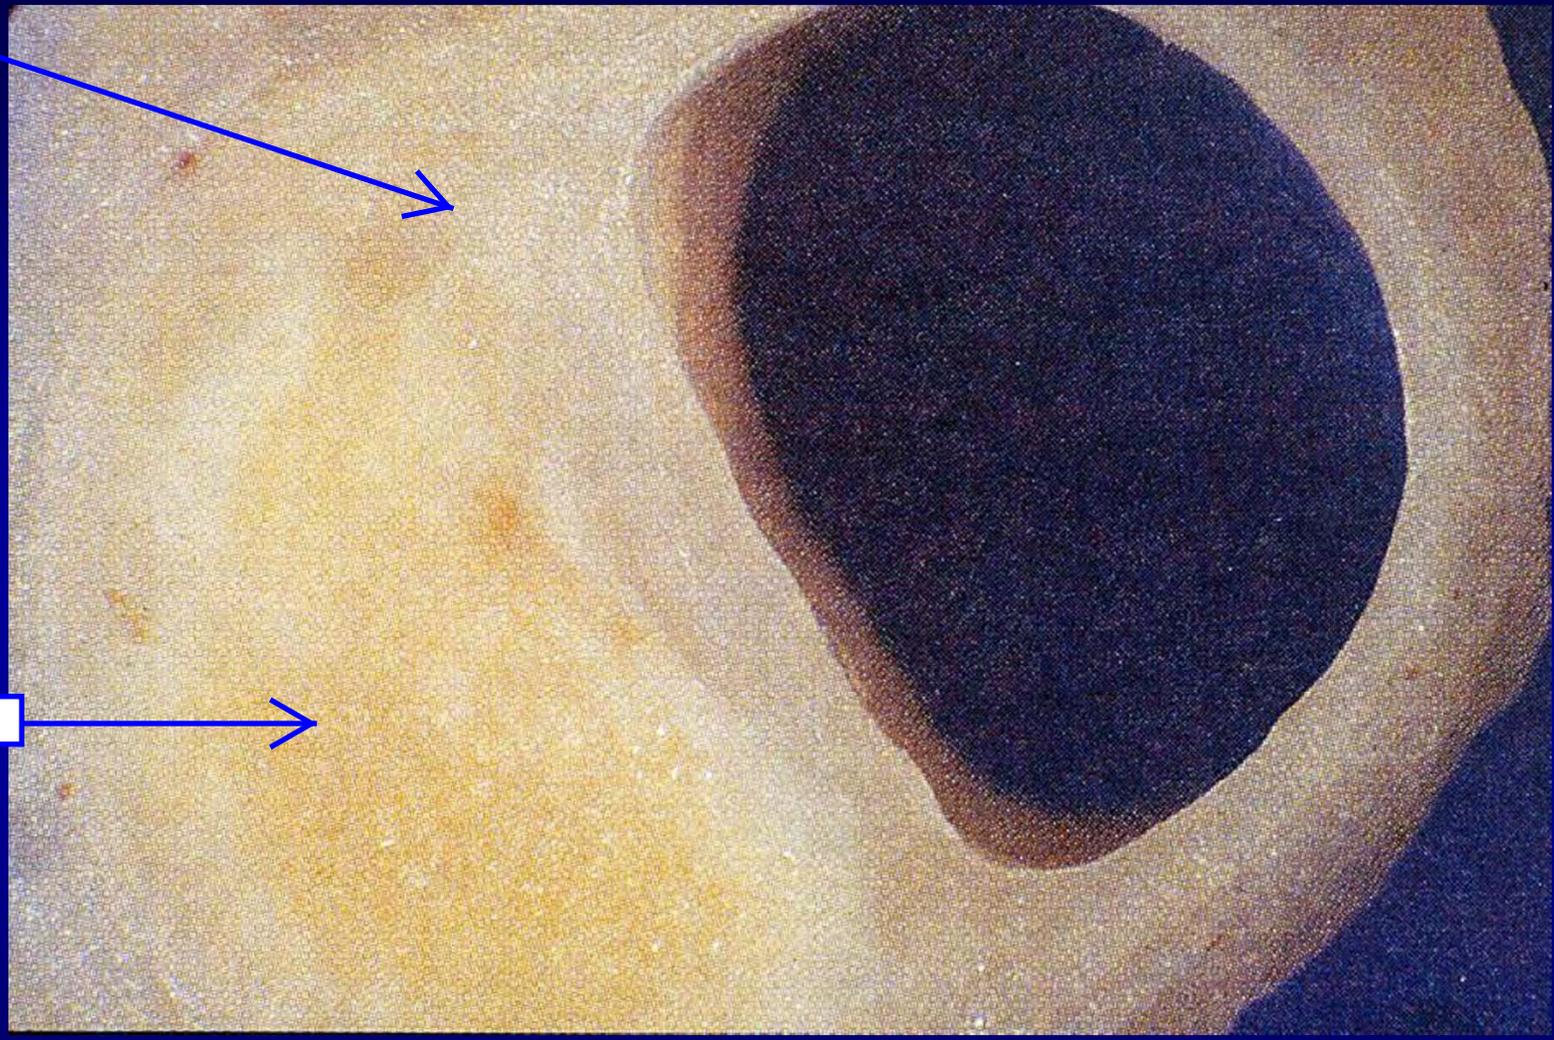

**INTRAPLAQUE
THROMBUS**

**PLATELETS
RED CELLS
FIBRIN**

**INTRALUMINAL
THROMBUS**

**FIBRIN/RED CELLS
(PLATELETS)**

Plaque with thin cap.

Fatty core.

Eccentric atherosclerotic plaque with lipid core

Ruptured atherosclerotic plaque with hemorrhage into plaque

Propagation into lumen

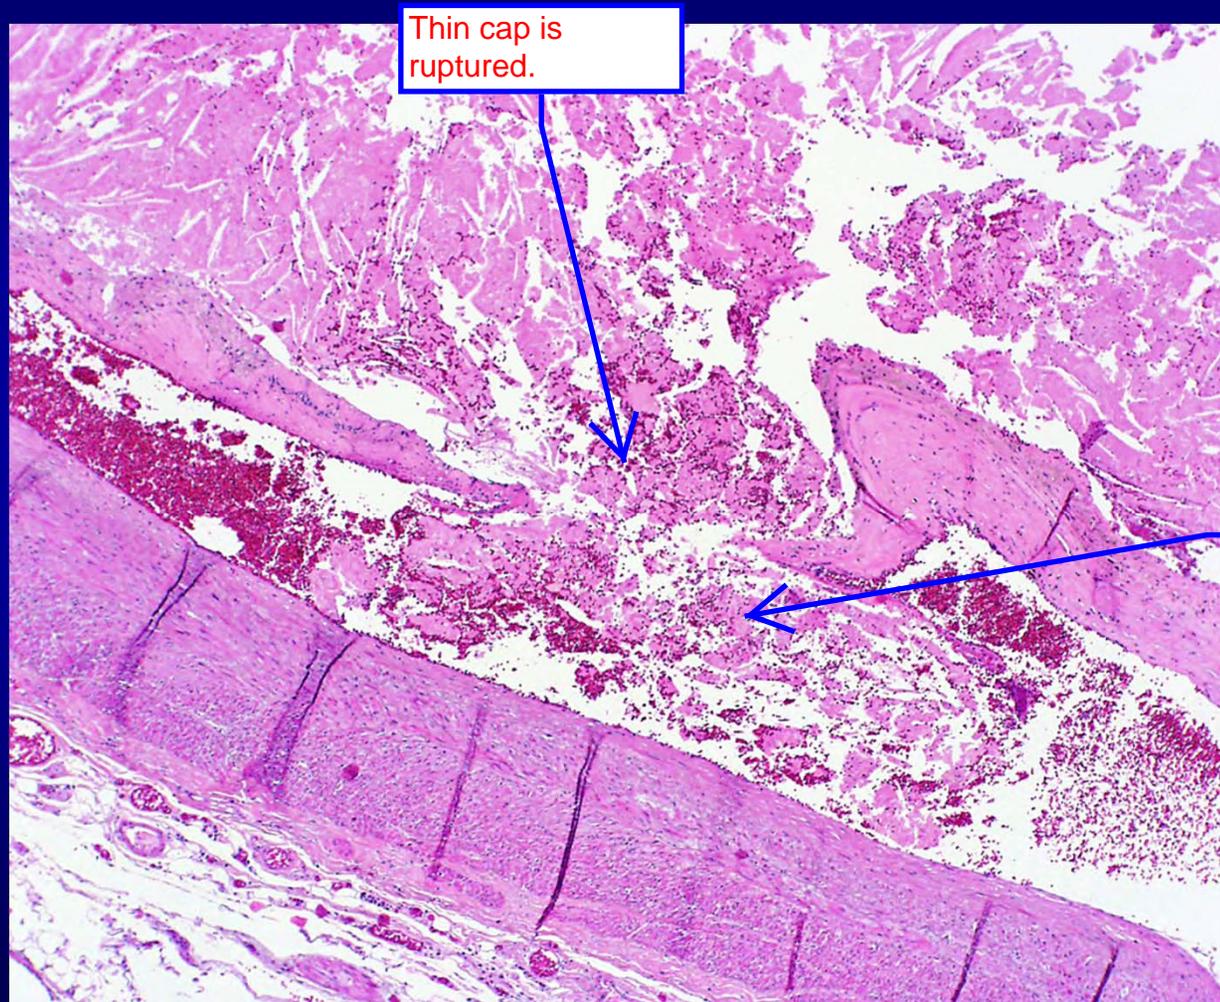

Ruptured atherosclerotic plaque with hemorrhage and thrombus on the surface

Plaque continues to propagate and causes acute stenosis.

Ruptured atherosclerotic plaque with hemorrhage and thrombus on the surface

Plaque Rupture and Thrombosis

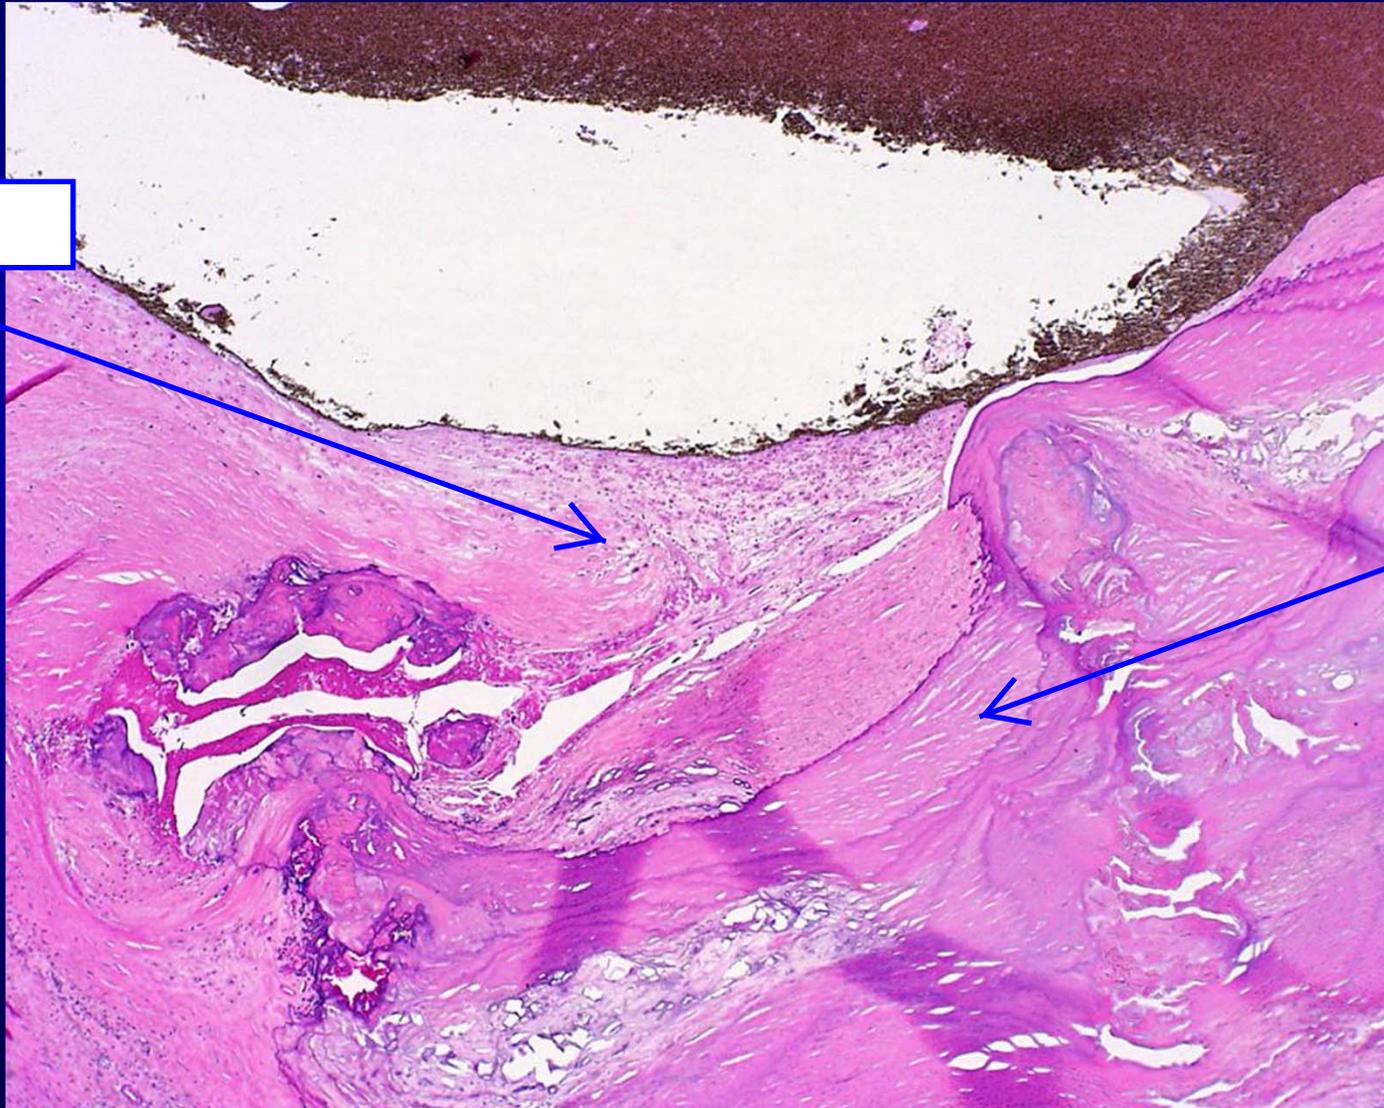

Thin cap is ruptured.

Fatty atheromatous material is being exuded into the lumen.

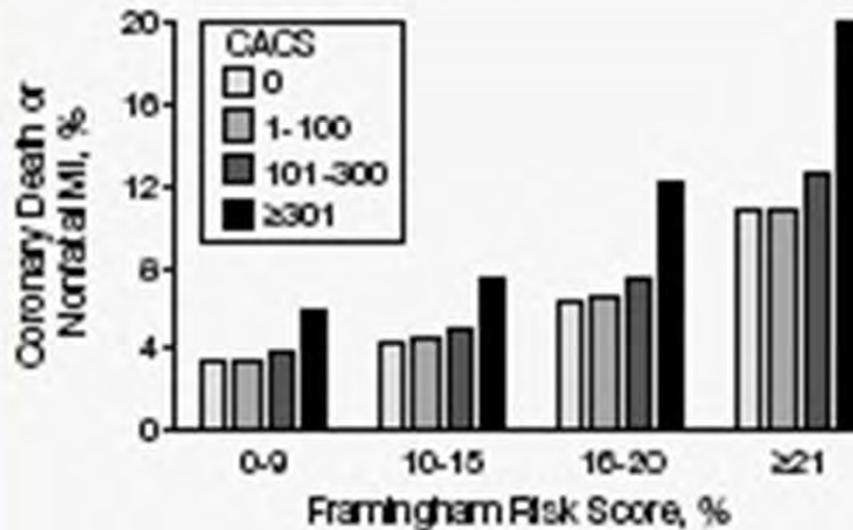

Plaque Calcification

Organizing thrombus.

Calcification down here.

Figure 1. Predicted 7-Year Event Rates From COX Regression Model for CHD Death or Nonfatal Myocardial Infarction for Categories of FRS or CACS

Coronary Artery Calcium Score Combined with Framingham Score for Risk Prediction in Asymptomatic Individuals. JAMA 2004; 291:210-215

Framingham Score

is based on the following risk factors: age, gender, diabetes, smoking history, blood pressure, total cholesterol, and LDL cholesterol

Coronary Artery Calcium Score (CACS)

is based on CT scan evaluation of coronary calcification

If you have many of these risk factors, you will have a much higher chance of cardiac death. Calcification increases the risk even more.

If you don't regularly exercise and then randomly exert yourself you have a much higher risk than a person that works out.

Triggers of SCD

Exertion: 6- 30%

- CAD/ plaque rupture; Neurogenic conditioning
- < weekly exercise: 75x risk, > 5/week: 11 x risk
- Overall: 1 SCD per 1,510,000 severe exertions

Sleep: 12%

- Increased occurrence for nonstructural disease

Stress

Sexual Activity:

- Low even with CAD

So don't worry too much.

Ischemia: How does it Kill?

- Arrhythmia (VF/VT) – 2 Phases:

- Substrate and Trigger

- 1A: **2 – 10 minutes post occlusion**

- Altered extracellular K^+ **affects refractory periods**
- **Injury Currents – normal cells reexcite prematurely**

- 1B: 18 – 30 minutes post occlusion (**greater role**)

- Epicardial cells demonstrate depression of excitability before mid and subendocardial cells
- Electrical signals produced **by unequal stretching** of cells at border of ischemic zone

Set up for ventricular fibrillation

2 important time periods for someone having an MI.

Cells are firing off too early

Creates gradient of excitability

Injured myocardium stretches differently from the healthy myocardium. That injury actually causes electrical signal, which is the trigger.

Ischemia: How does it Kill?

Later deaths

- Infarcts – **Prior scar creates reentry paths**

- Autonomic Denervation

- Baroreflex Sensitivity: **Vagal protection loss**
- Nerve “Sprouting”: sympathetic reinnervation post MI demonstrated with marker studies.

Lose the ability of the vagus nerve to tell the heart to chill out.

Overgrowth of sympathetic nerves that stimulate the heart.

- Ventricular Dysfunction - ↓ LVF, Regurg

When you have death of a bunch of myocardial cells.

MANAGEMENT OF ACS RELATED SUDDEN CARDIAC DEATH

Prevention of IHD (Risk factor control)

Identification of High Risk Patients

Prophylactic drug therapy (β blockers)

Implantable automatic defibrillator

**Rapid Resuscitation (each minute of VF
decreases survival rate by 7-10%)**

Best thing to do is
defibrillate a patient to
save their life.

ISCHEMIC HEART DISEASE

Pathology of Myocardial Infarcts

Heart will undergo coagulative necrosis first, then there is inflammation then there is cleanup by macrophages and scar formation.

Patient Prognosis is Inversely Related to Infarct Size

Larger Infarcts:

Higher frequency of arrhythmias

Higher frequency of hemodynamic complications

Higher short-term mortality

**Cardiogenic Shock is usually associated with
infarcts occupying $> 30\%$ (mean = 40%) of the
Left Ventricle**

Gross Pathology: Determinants of Infarct Size

Size of the Vascular Territory involved (Area at Risk)

Larger infarct if the occlusion is proximal rather than distal because it supplies a larger territory.

Duration of Ischemia: Wavefront Phenomenon

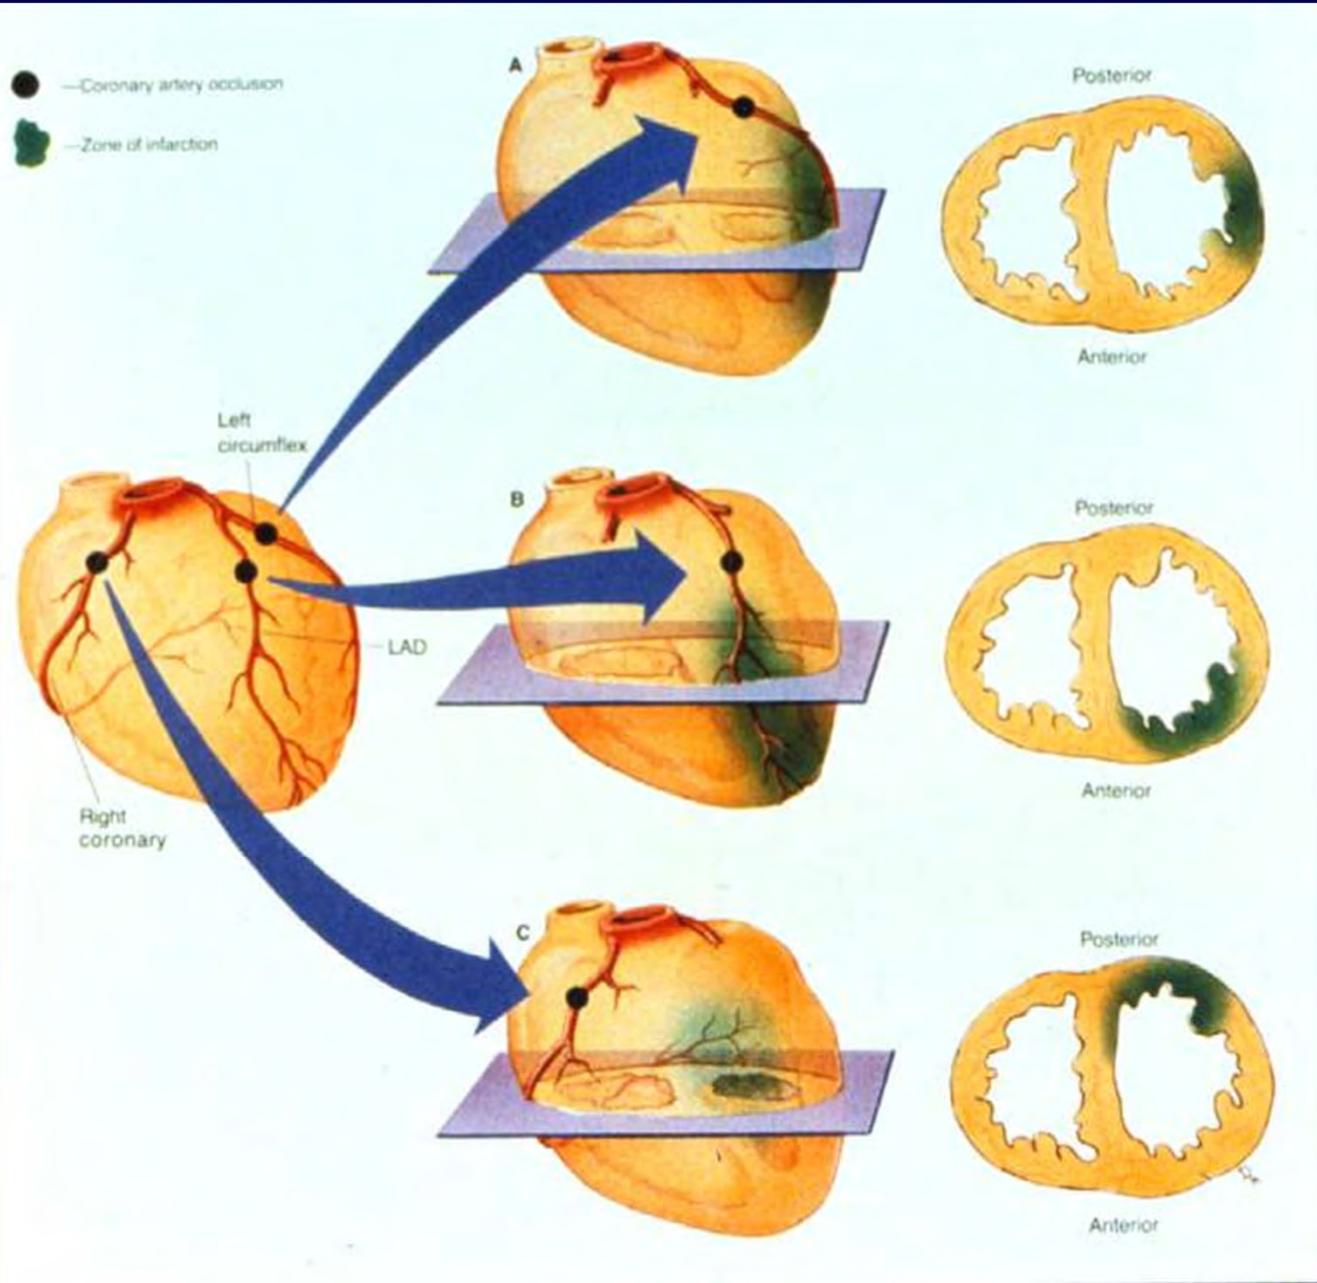

Magnitude of Collateral Blood Flow to the Area at Risk

Can slow down the progression of an MI

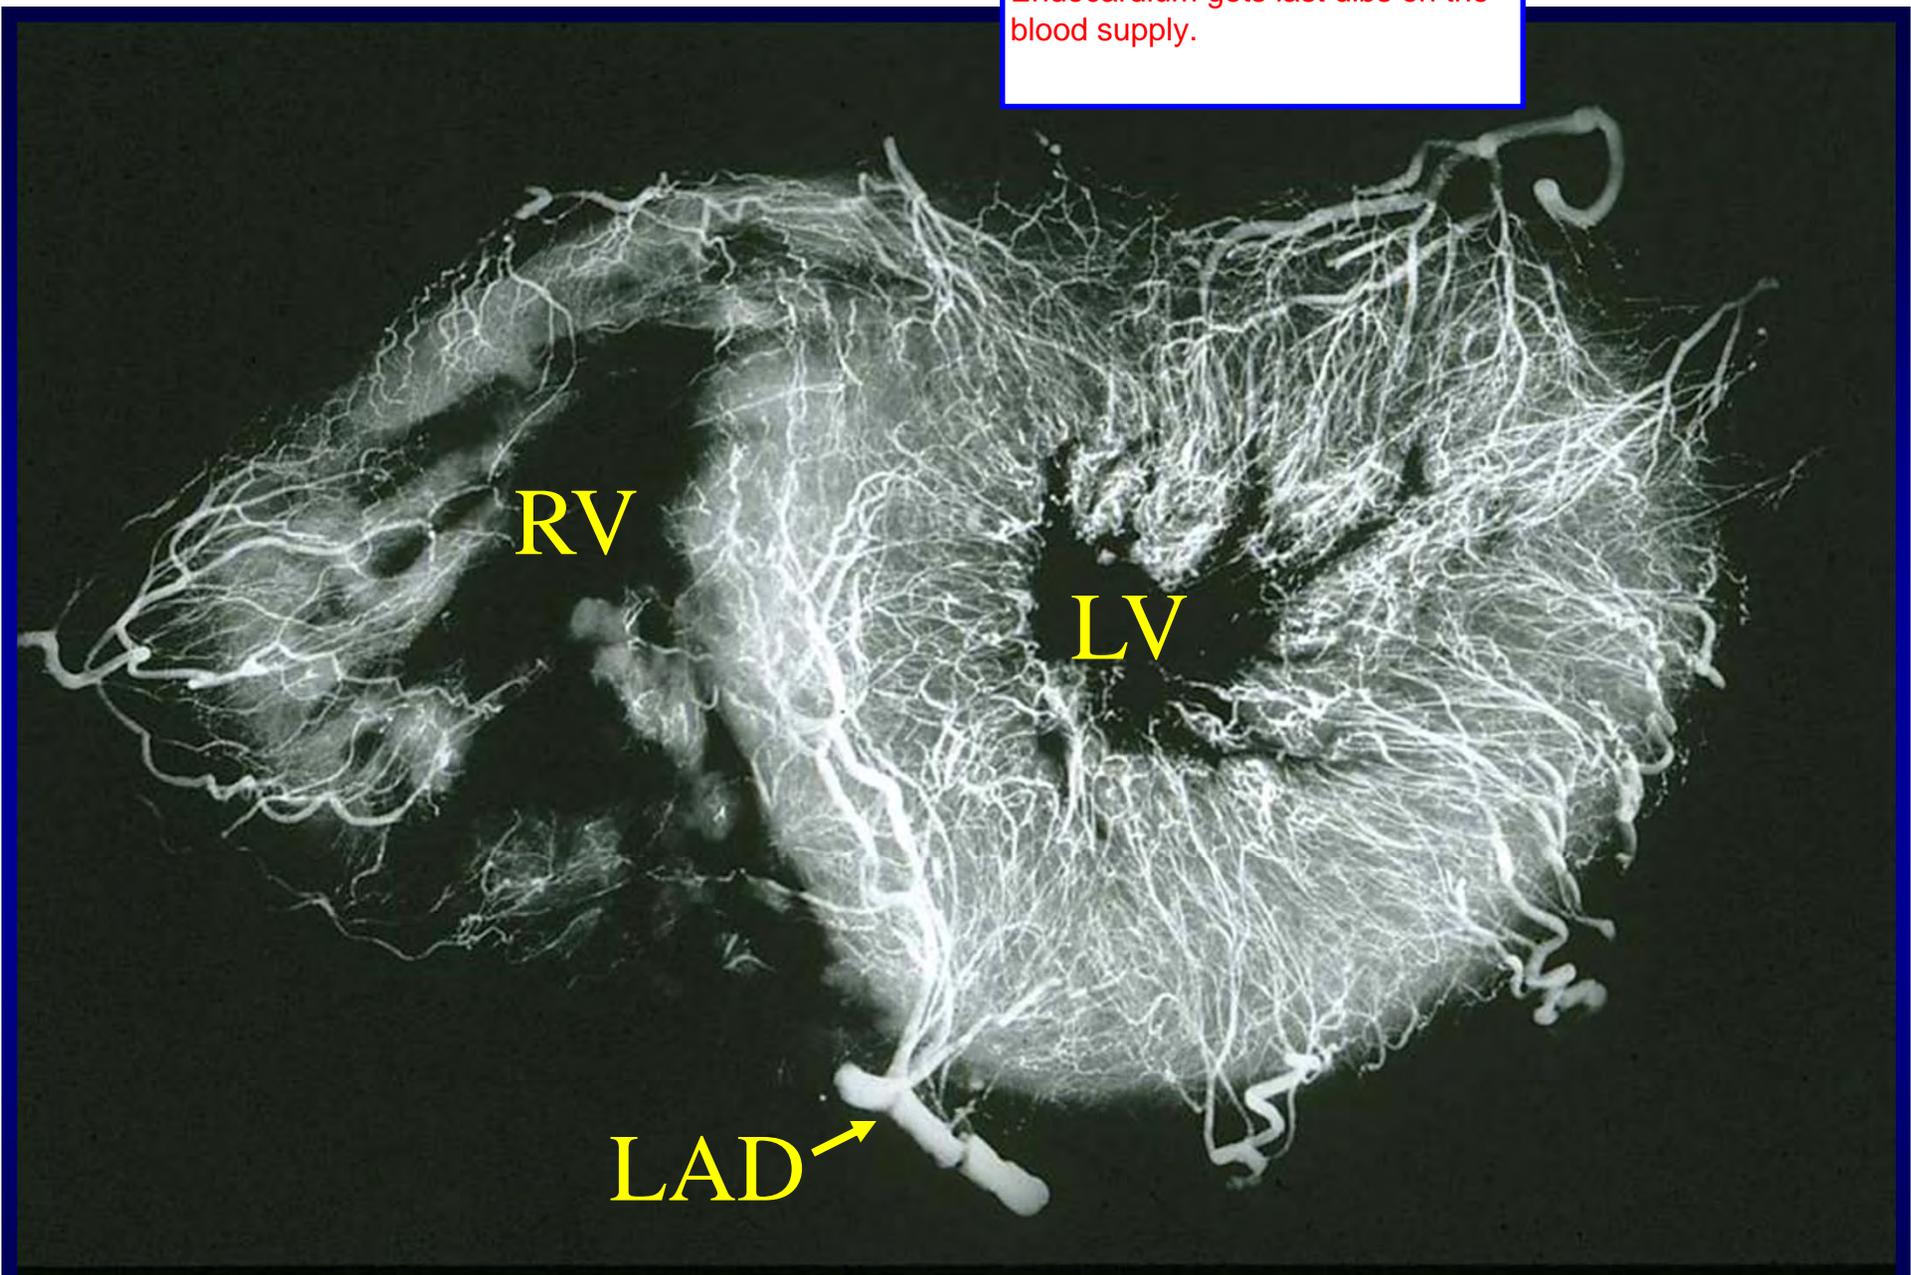

Metabolic Rate of Myocardium during Ischemia

- Hemodynamic Determinants - Heart rate, Systolic LV pressure, Contractile state
- Myocardial Temperature

How hard was the heart working before losing blood flow? In a person that was sleeping it will take longer for the infarct to develop, than if the person was exercising.

Endocardium gets last dibs on the blood supply.

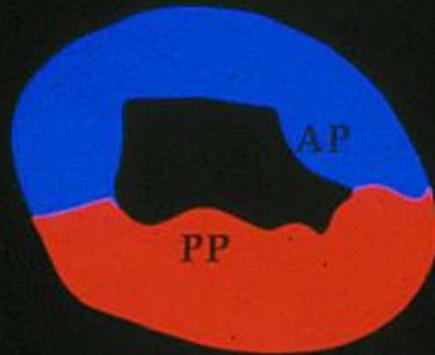

Coronary artery angiogram (slice through the ventricles)

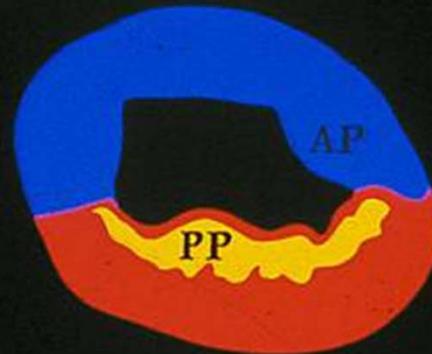

From the paper discussing wavefront phenomenon, which was discovered at Duke.

MYOCARDIAL INFARCT SIZE AFTER ISCHEMIA (I) AND REPERFUSION (R)

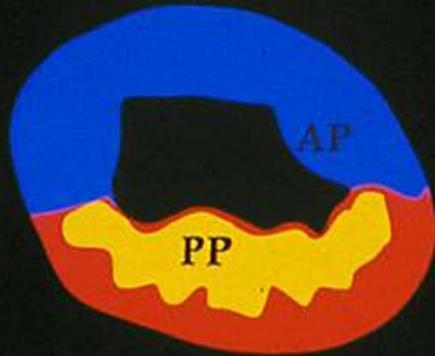

15 min I
+ R

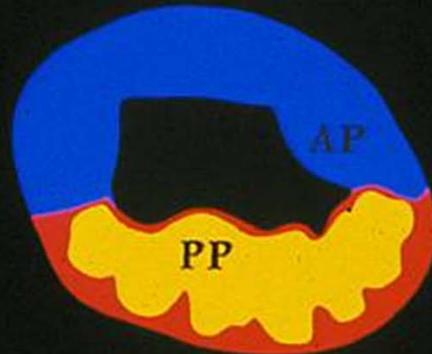

40 min I
+ R

3 hrs I
+ R

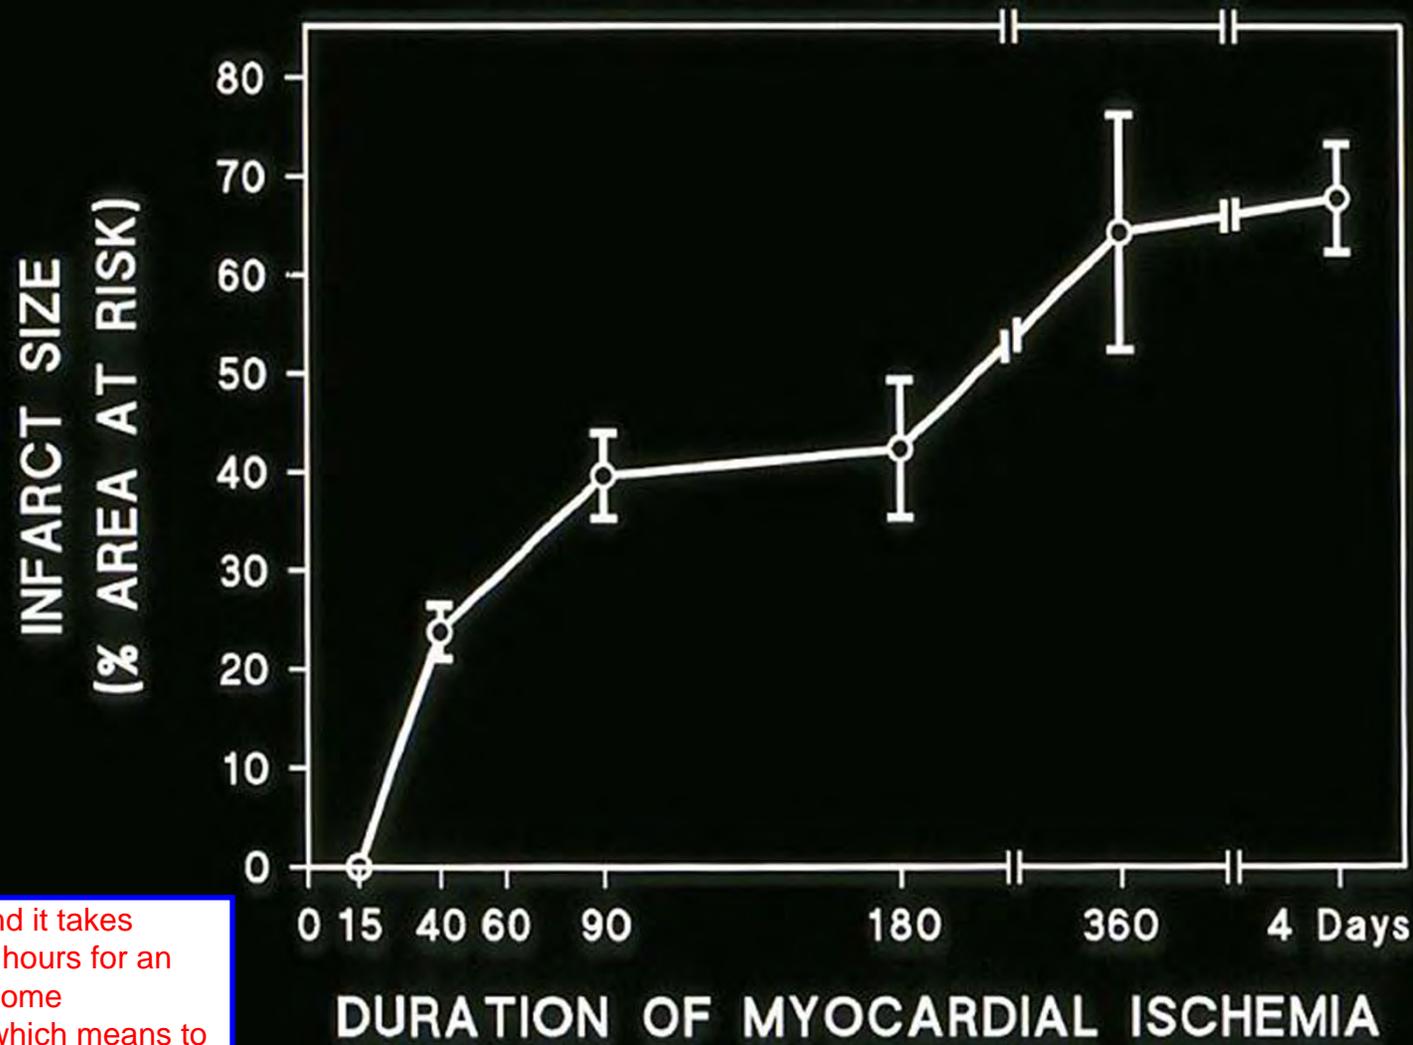

4 days I;
no R

■ Nonischemic ■ Occluded Vascular Bed (area at risk) ■ Infarct

Prior to this people thought the whole area perfused by a certain artery dies off at the same time. The Duke researchers showed that it progresses as a wavefront starting from the endocardium, which gets blood flow last, and is under more stress so requires more oxygen. Then the infarct progresses to the epicardium.

EFFECT OF DURATION OF MYOCARDIAL ISCHEMIA ON INFARCT SIZE IN DOGS

1.) They found it takes between 3-6 hours for an infarct to become transmural, which means to cover a majority of the space from the inner to the outer wall.

2.) That's why you rush people in the ER with an infarct to the cath lab because you have a small window where you can save some myocardial tissue. Collaterals can extend this window even more.

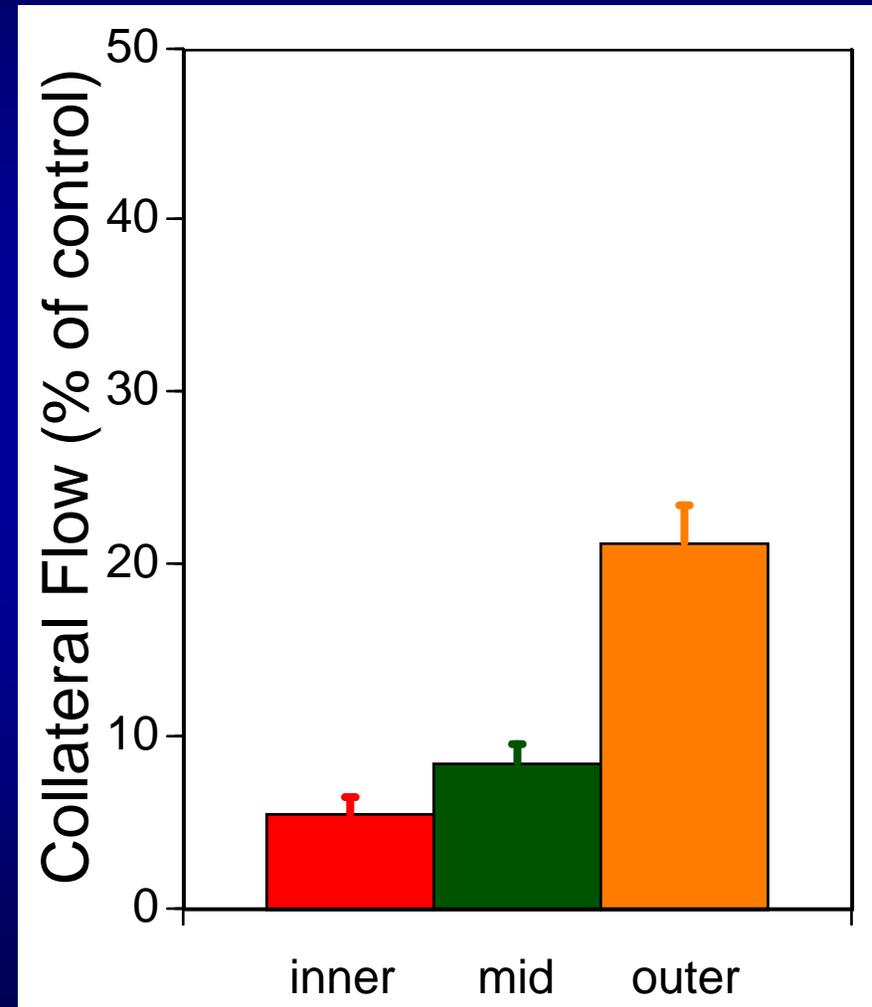

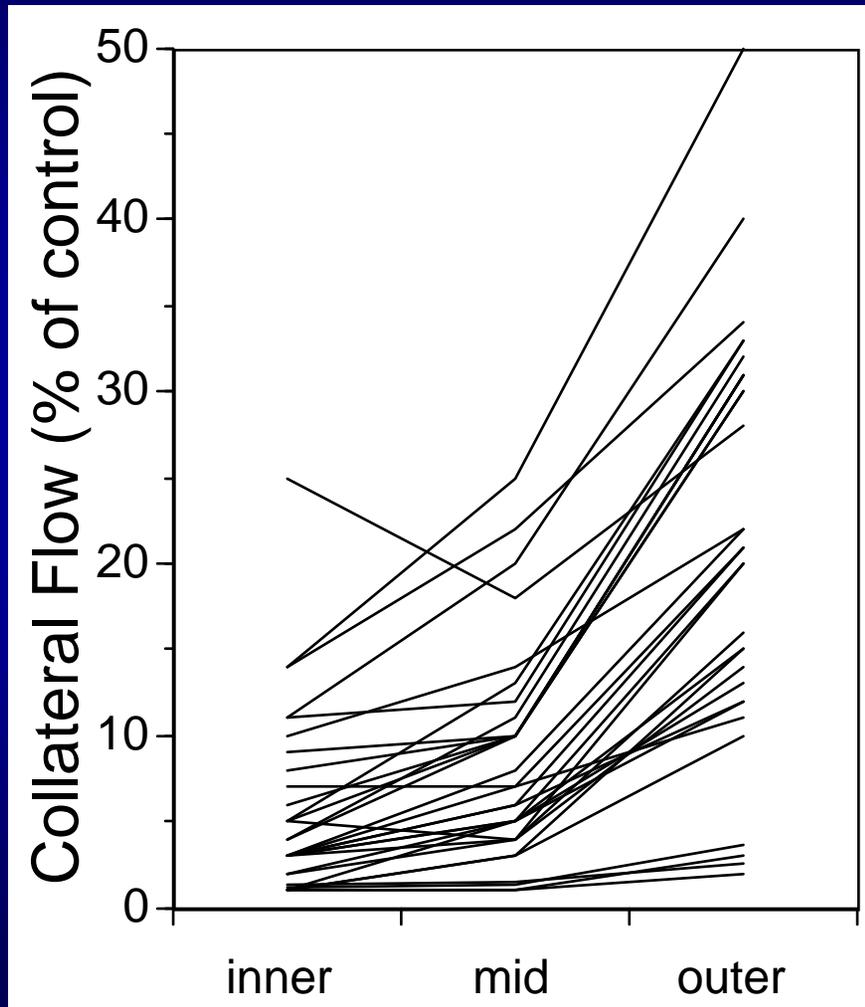

Relationship between Collateral Flow and Infarct Size

Collateral flow is highest in the outer layer of the myocardium; if collateral flow is high enough, the infarct will not be transmural regardless of duration.

Gradual stenosis of a coronary artery promotes the development of collateral circulation.

Some patients with virtually complete occlusion of a major coronary artery do not have an infarct.

Collateral Flow in Different Layers (inner third, middle third, outer third) of the Myocardium following Coronary Occlusion

Dating Myocardial Infarcts

- **Importance**
 - Potential for intervention/myocardium salvage
 - Forensic: Cause of death vs. Contributing Factor
 - Medico-legal: Assess Negligence
- **Assessment**
 - History: Risk Factors, HPI, Physical Exam, Labs
 - Gross: Autopsy > Surgical Specimens
 - Histology: Routine and Special Stains

MI: Gross Appearance

If blood flow is restored, it can heal quicker and you will have different features than if blood flow was not restored.

- **REPERFUSION? – Key question**

- Pallor vs. Hemorrhage
- Timing of Reperfusion/Ischemia
- Border vs. Central Healing

Healing occurs from outside in.

- **Acute findings**

- **May be absent**
- Pallor or hemorrhage
 - **Inflammation → Myophagocytosis**

-When no reperfusion, there is low blood flow, and low risk of hemorrhage.
-When you do have reperfusion, blood vessels are often injured and will leak. So restoration of blood flow leads to hemorrhagic infarcts.
-May also see contraction band necrosis where reperfusion causes calcium flux and the contractile fibers in necrotic myocytes over-contract and you get these dense bands.

May not see anything within the first 4-6 hours because it takes time for necrosis and inflammation to set in.

- **Subacute**

- Granulation tissue **scarring**
- Mummified myocytes

- **Advanced healing – Mature fibrous scar**

- Fatty change – mesenchymal differentiation

some people get really fatty infarcts

Just pay attention to the yellow words and times.

Morphologic Stages of Myocardial Infarction: Inflammatory Response and Repair

-This is what generally happens in non-reperfused infarcts.

- 0 - 6 hours **No Change** (Gross or Microscopic)
- 6 - 24 hours +/- “Wavy-fiber Change”
Early features of **Coagulative Necrosis** (Cytoplasmic eosinophilia; Nuclear pyknosis followed by karyolysis)
- 1 - 4 days Coagulative Necrosis with **Acute Inflammatory Response** (mostly neutrophils) - maximum influx at 2 - 3 days; neutrophils intact at first, disintegrating by 3 - 5 days
- 5 - 7 days **Macrophage Activity** (phagocytic removal of dead myocytes, pigmented macrophages increasing)
- 7 - 10 days Developing peripheral rim of **Granulation Tissue**
- 1 - 6 weeks Progressive **Organization** of infarct
- 1 - 3 months Progressive **Collagen Deposition, Mature replacement scar**

***Consider Variable Reperfusion, Interventions and Infarct Size**

Dating Myocardial Infarcts

Who cares?

Case

- 47 yo male with a history of hypertension, tobacco abuse presents with reported new onset chest pain.
- He is worked up for cardiac as well as pulmonary and GI disease
- An ECG and Cardiac enzymes are eventually performed and are noted to be positive 12 hours after admission
- The patient is taken for cardiac catheterization where a thrombus in the LAD is treated with angioplasty and stenting. Did the right thing, but somewhat delayed.
- The patient has continued low ventricular function and succumbs that night to severe cardiogenic shock

Now Who Cares?

F & G FAISON &
GILLESPIE

Who *REALLY* Cares?

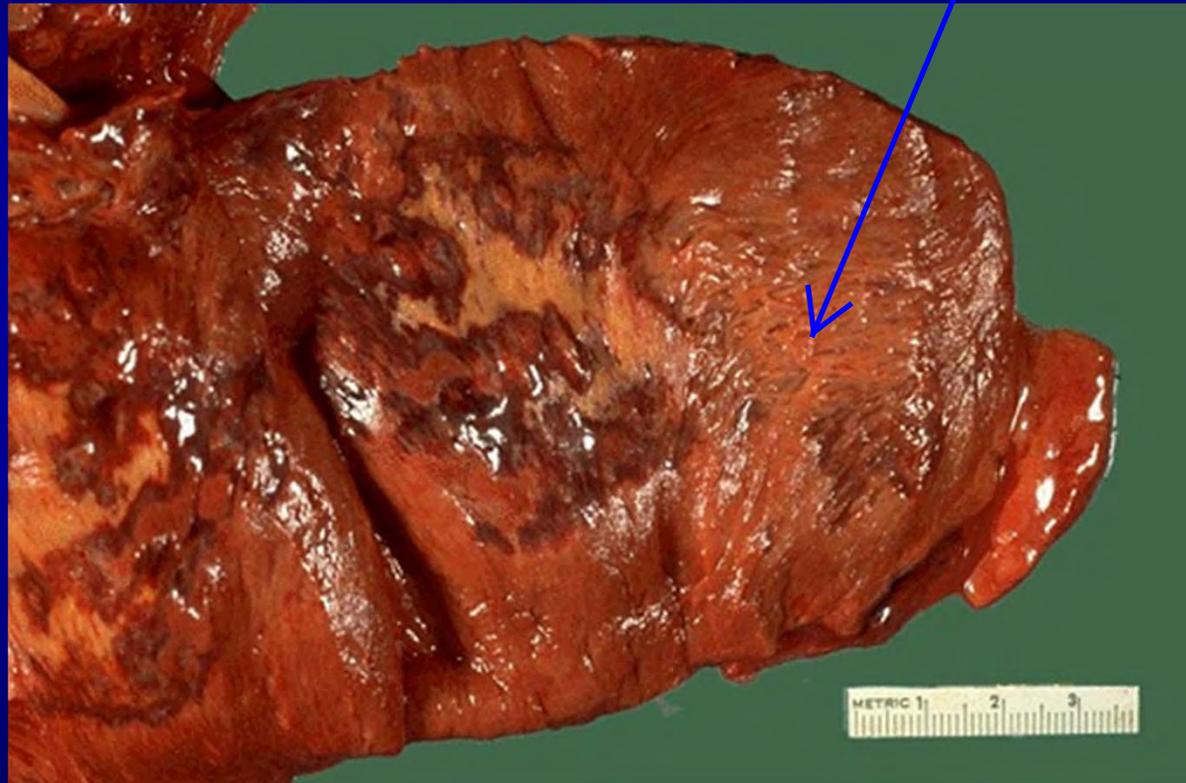

©1998-2003 Charles Frey <charles@charles.cc>

Pathology Scenario A

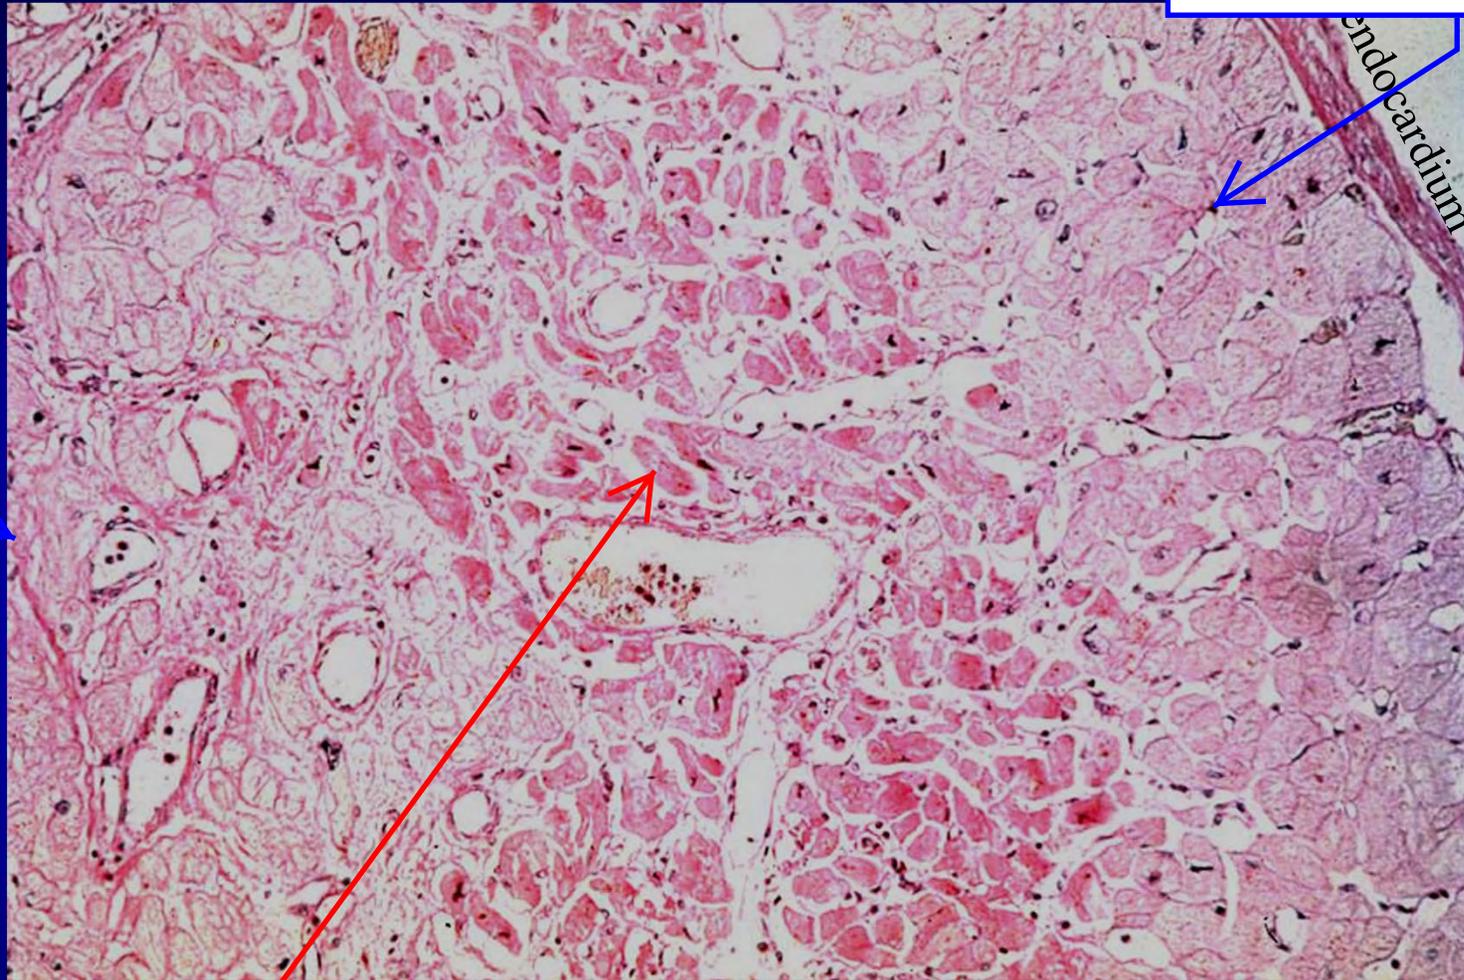

Acute MI

MI

Pallor with hyperemic border

Viable myocardium under endocardium surface because oxygen can directly diffuse into these cells from the ventricular chamber.

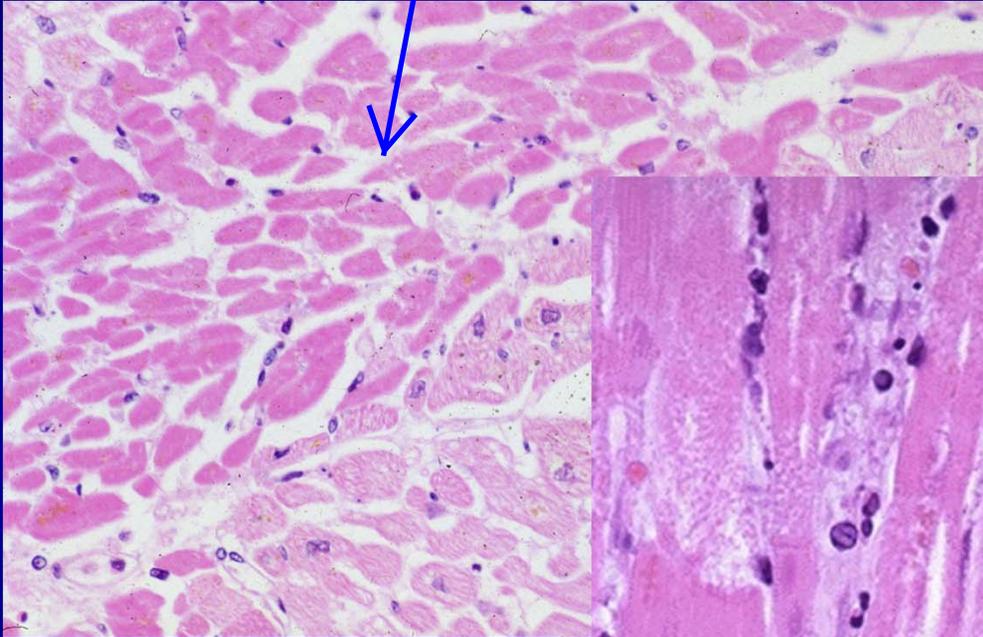

More viable cells

H&E stained section of subendocardium with hyper-eosinophilic necrotic myocytes, separated from the endocardium by a layer of intact myocytes.

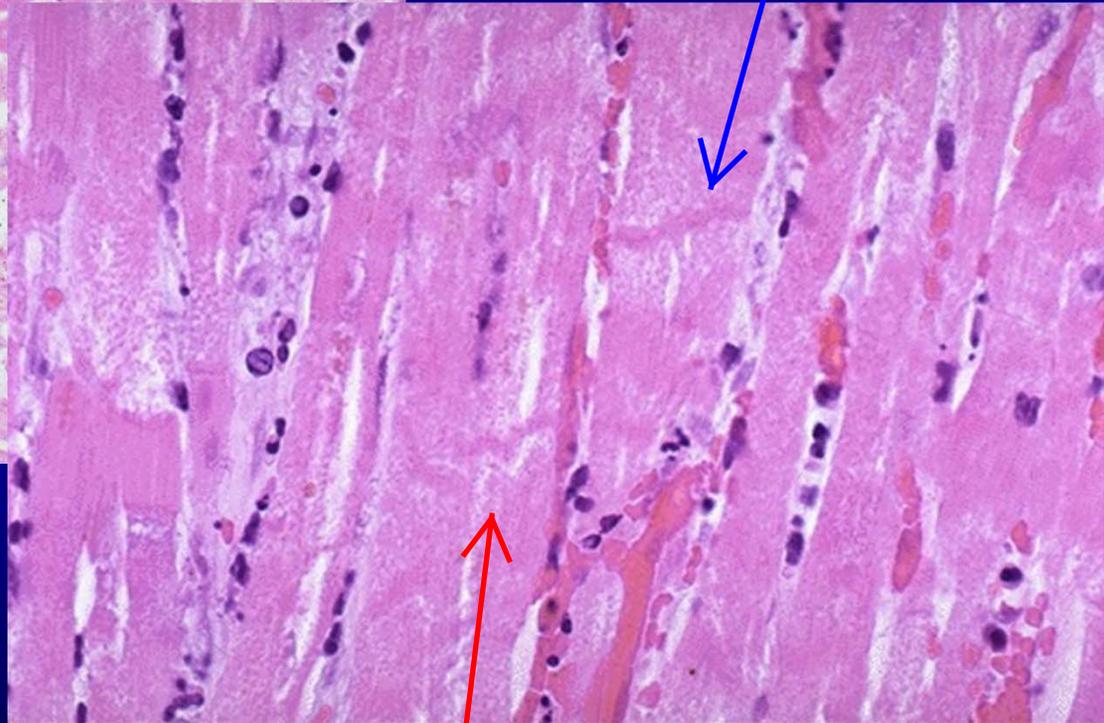

Acute MI

More pink, loss of nuclei,

Contraction band, can have them in infarcts that aren't completely reperfused.

Hyper-eosinophilia

Contraction bands

RESULT:

Pathology Scenario B

3-4 day old myocardial infarct with early karyolysis and numerous neutrophils

Pallor with influx of neutrophils

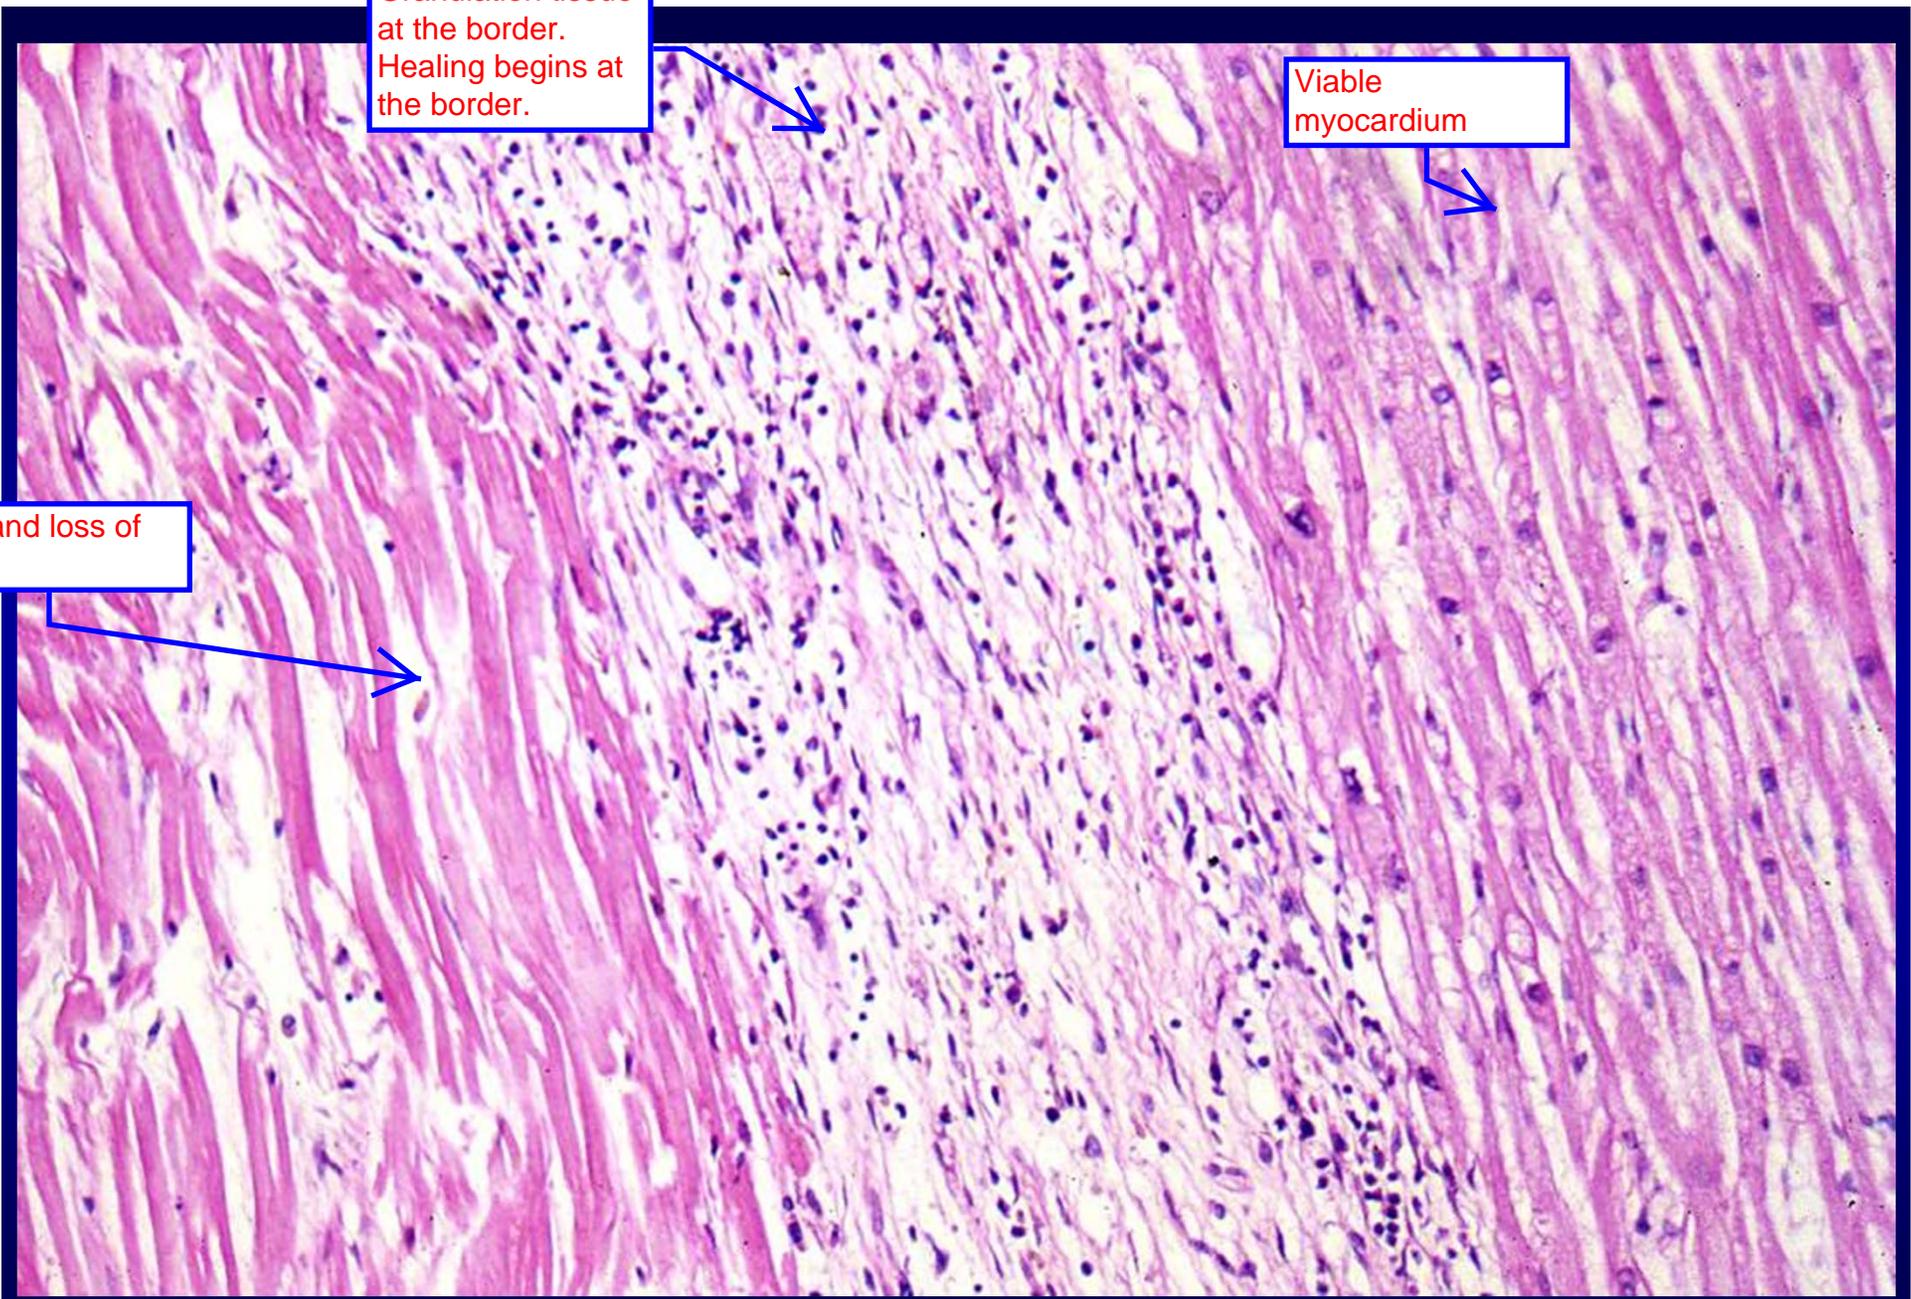

Subacute posteroseptal infarct (yellow discoloration)

Granulation tissue
at the border.
Healing begins at
the border.

Viable
myocardium

Pink and loss of
nuclei

Granulation tissue repair at the interface between viable and necrotic myocytes

Grayish look is
what granulation
tissue looks like

Organizing anteroseptal MI; healed posteroseptal MI with aneurysmal thinning

Old infarct that was not recognized by patient or physician

Healed posteroseptal MI with aneurysmal thinning

RESULT:

Pathologic findings indicate infarct was maximal size at time of presentation to ER

Possibly also shows prior large healed infarcts

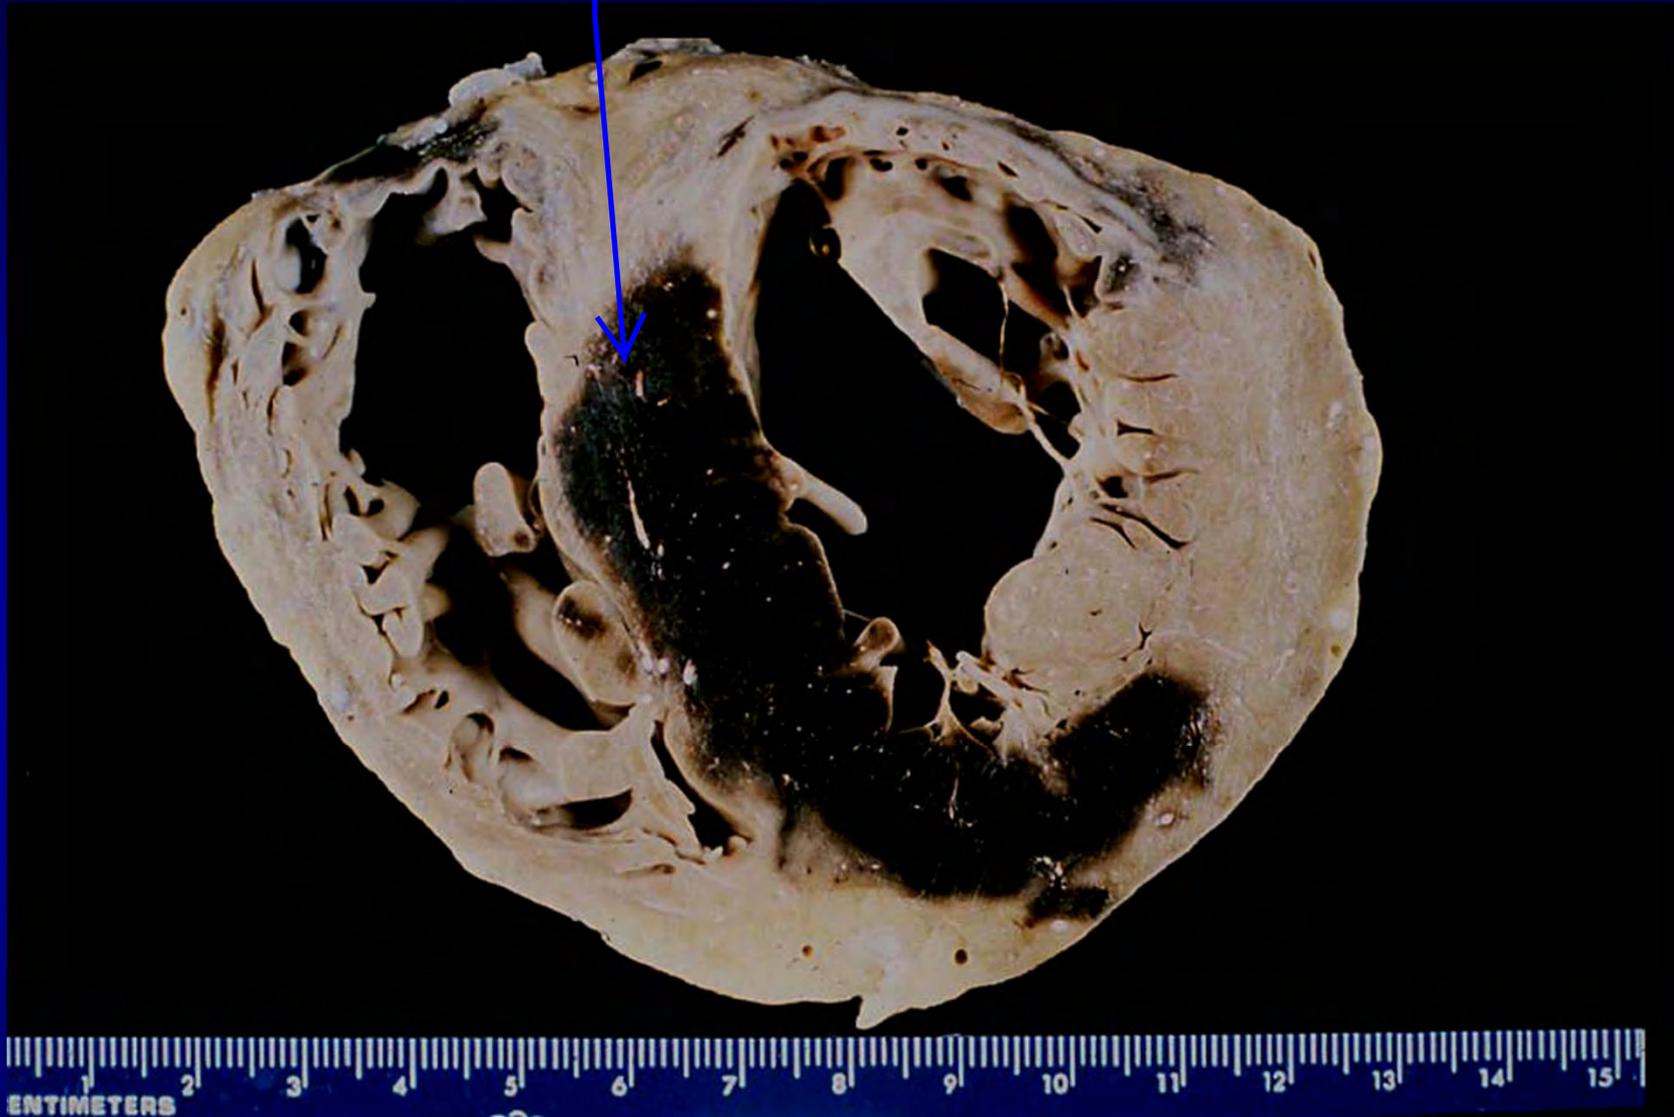

“ The Miscarriage of Justice”

REPERFUSION

1. Accelerates disintegration of irreversibly injured myocytes (causes contraction band necrosis)
2. May accentuate hemorrhage into areas of microvascular injury (causes hemorrhagic infarct)
3. May or may not cause lethal reperfusion injury
4. Limits myocardial infarct size if early enough
5. Supports slow metabolic and contractile recovery of viable myocytes (stunning)

Cells that are not fully injured become irreversibly injured by reperfusion bc of stimulation of Nitric oxide and physical obstruction.

Reperfused infarct
with massive
hemorrhaging.

Acute anteroseptal MI with hemorrhage following late thrombolytic therapy

Interventions to Limit Myocardial Infarct Size

Restoration of Myocardial Perfusion

- Thrombolytic Therapy
- Emergency Coronary Angioplasty

Adjunctive Therapy

- To delay lethal myocyte injury until reperfusion has been achieved
- To prevent lethal reperfusion injury

Myocardial Infarction - Mortality & Morbidity

Acute In-hospital Mortality - 7%

One Year Mortality - 35%

Arrhythmias - 40 - 50 % of deaths

Pump Failure - 40 - 45 % of deaths

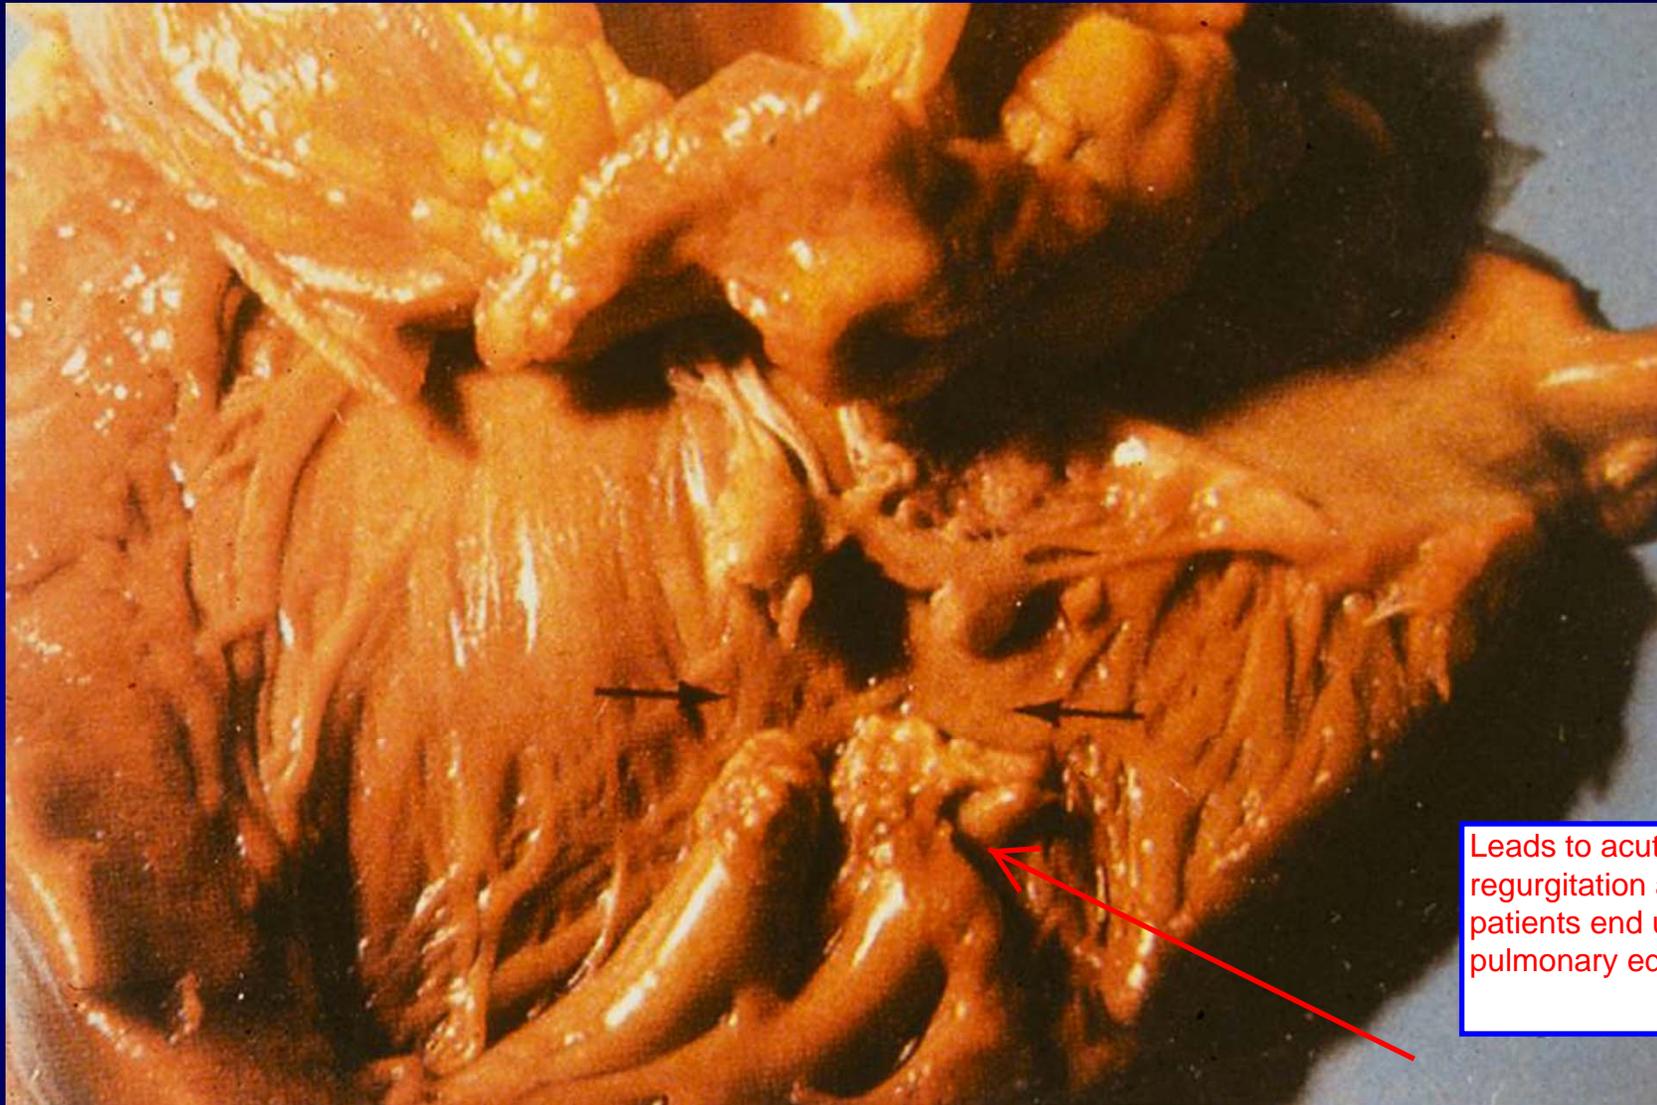

- **Cardiogenic Shock**
- **Congestive Heart Failure - 20 % of patients surviving MI develop CHF**

Other Complications

- **Rupture - LV free wall, interventricular septum, or papillary muscle**
- **Mitral insufficiency**
- **Ventricular Aneurysm**
- **Mural Thrombosis**

Acute
infarct of
the lateral
wall of
the left
ventricle
with
rupture of
the wall

Leads to acute mitral regurgitation and patients end up dying of pulmonary edema.

Ruptured papillary muscle following acute MI

Healed
transmural
apical
infarct of
the left
ventricle
with
aneurysm
and
laminated
mural
thrombus
in the
apex

Cardiomyopathies

dysfunction of the heart muscle itself.

- **LVEF most powerful risk stratifier**
 - **≤ 30% improved survival with ICD placement**

- **Ischemic:**
 - **Scarring**
 - **Arrhythmia**
 - **Aneurysm**
 - **CHF**

Hypertrophic Cardiomyopathy

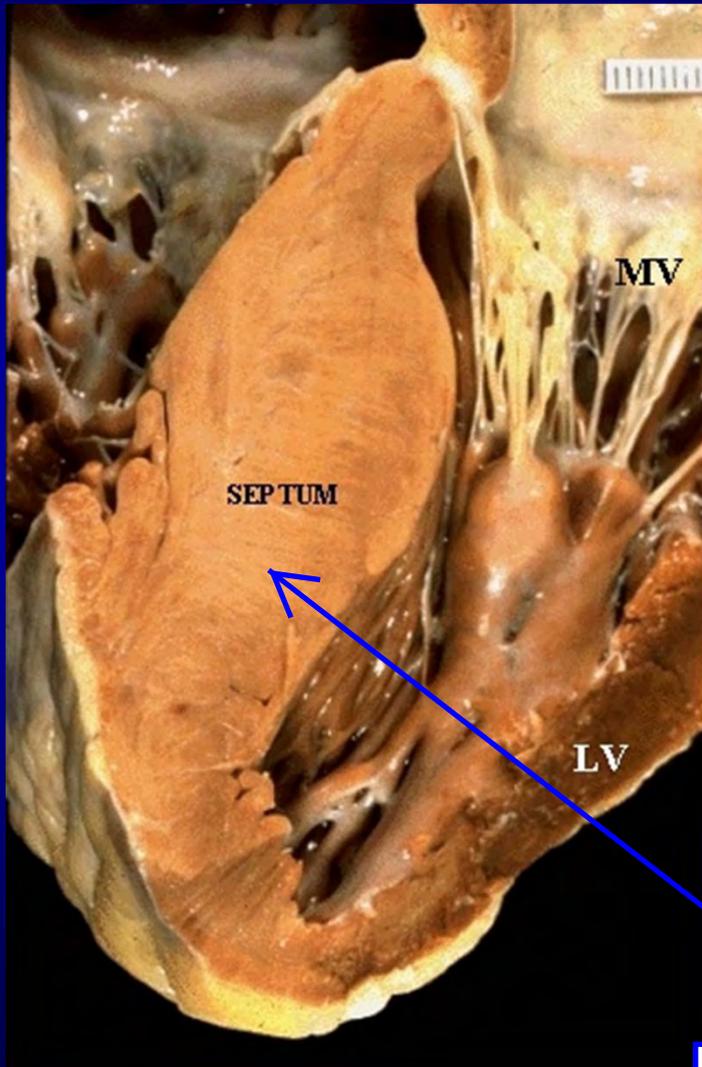

- Classic Form – Asymmetric vs Concentric
- Incidence 0.2%
- Genetics: Cardiac sarcomere proteins:
 - β myosin heavy chain
 - Myosin binding protein C
 - **Cardiac troponin T and I (\uparrow SCD)**
 - α -tropomyosin
- Frequently **autosomal dominant** with 55% penetrance by age 30
- Phenotypes may be markedly different

Involves septum more than the ventricle.

-These are the athletes that die suddenly.
-Shows up at a pretty young age.

Different in terms of extent of fibrosis and enlargement

Hypertrophic Cardiomyopathy: Gross

Asymmetric

Thickness > 3.0 cm high risk

***But Majority of SCD
at lesser thicknesses**

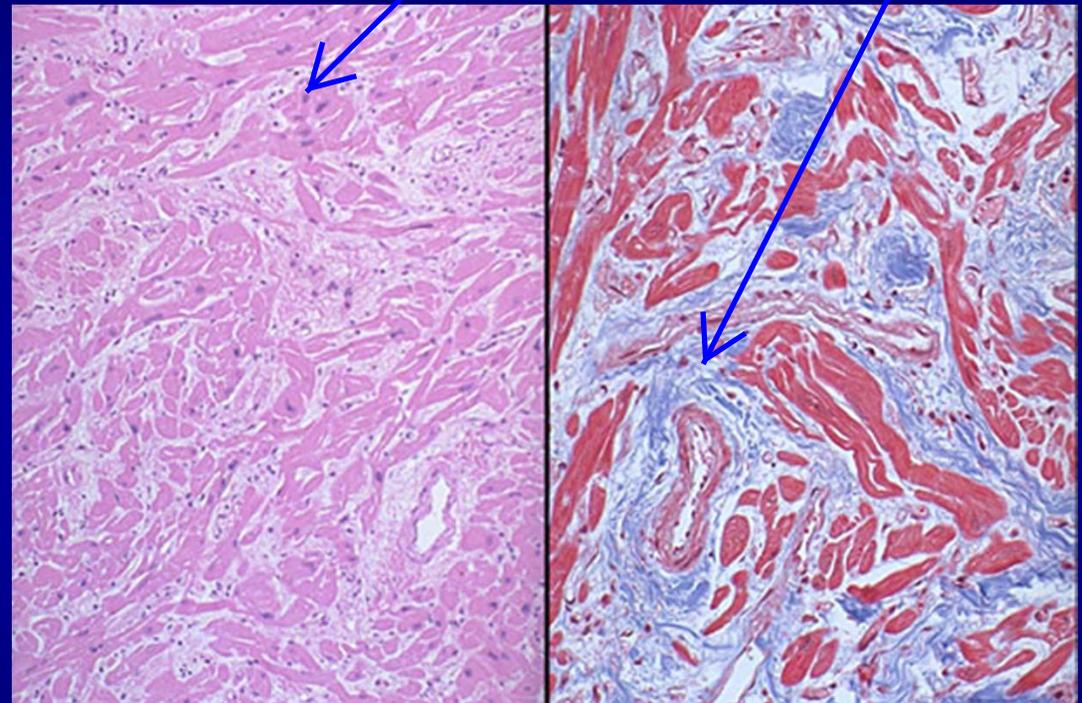

Degree of LVOT obstruction

Treatment is to go
in and shave the
muscle down.

Large lump of
muscle blocks
outflow into the
aorta.

Hypertrophic Cardiomyopathy

- **Histology:**
 - Myocyte hypertrophy
 - Disarray
 - Fibrosis
 - Small vessel disease

Disarray and look like the myocytes are oriented at a bunch of different angles.

Fibrosis and scarring in small vessels.

Degree of hypertrophy and fibrosis is variable

“Burnt out” phase – fibrosis with wall thinning

Ends up looking dilated

Screening?

- **Practical only when limited by Family History**

Don't really do any screening besides family history.

- **Risk SCD in HS athletes 0.46/100,000**
- **USAF basic training 1.2/100,000**
- **Italian study suggests benefits to ECG screening of athletes – Only subset with identifiable hypertrophy prior to risk SCD**

Other Hypertrophic CM's

- **HYPERTENSIVE**
 - **Concentric**, requires \uparrow preload
 - Increased susc. to ischemia/hypoxia
- **Storage Disorders** – enzyme deficiencies:
 - Fabry's disease (α -galactosidase)
 - Pompe's disease (α -1,4-glucosidase)
 - Other Glycogen Storage Disorders
 - LAMP2 (Danon's disease)
 - PRKAG2
 - Both associated with VF/VT with hypertrophy and diminished extracardiac lesions

All can lead to hypertrophy and sudden cardiac death.

Often time heart is the only organ affected.

Dilated Cardiomyopathy

- Less well-delineated causes
- Less unexpected sudden death though can occur with arrhythmias
- Myocarditis “inflammatory cardiomyopathy”
 - Enterovirus, Adenovirus, Influenza, HIV
 - Protozoan – Toxoplasma, Trypanosoma (Chagas)
- **Toxic: Alcohol, Iron**

Cardiomyopathy: ARVD

- **Arrhythmogenic Right Ventricular Dysplasia**
 - Fibrofatty replacement with thinning
 - “Triangle of Dysplasia”: Inflow, outflow, apex
 - **Frequent VT in young adults**
 - If survive may progress to RV failure
 - Ultimately involves LV failure

Major and Minor Criteria include Gross, EP, Hx

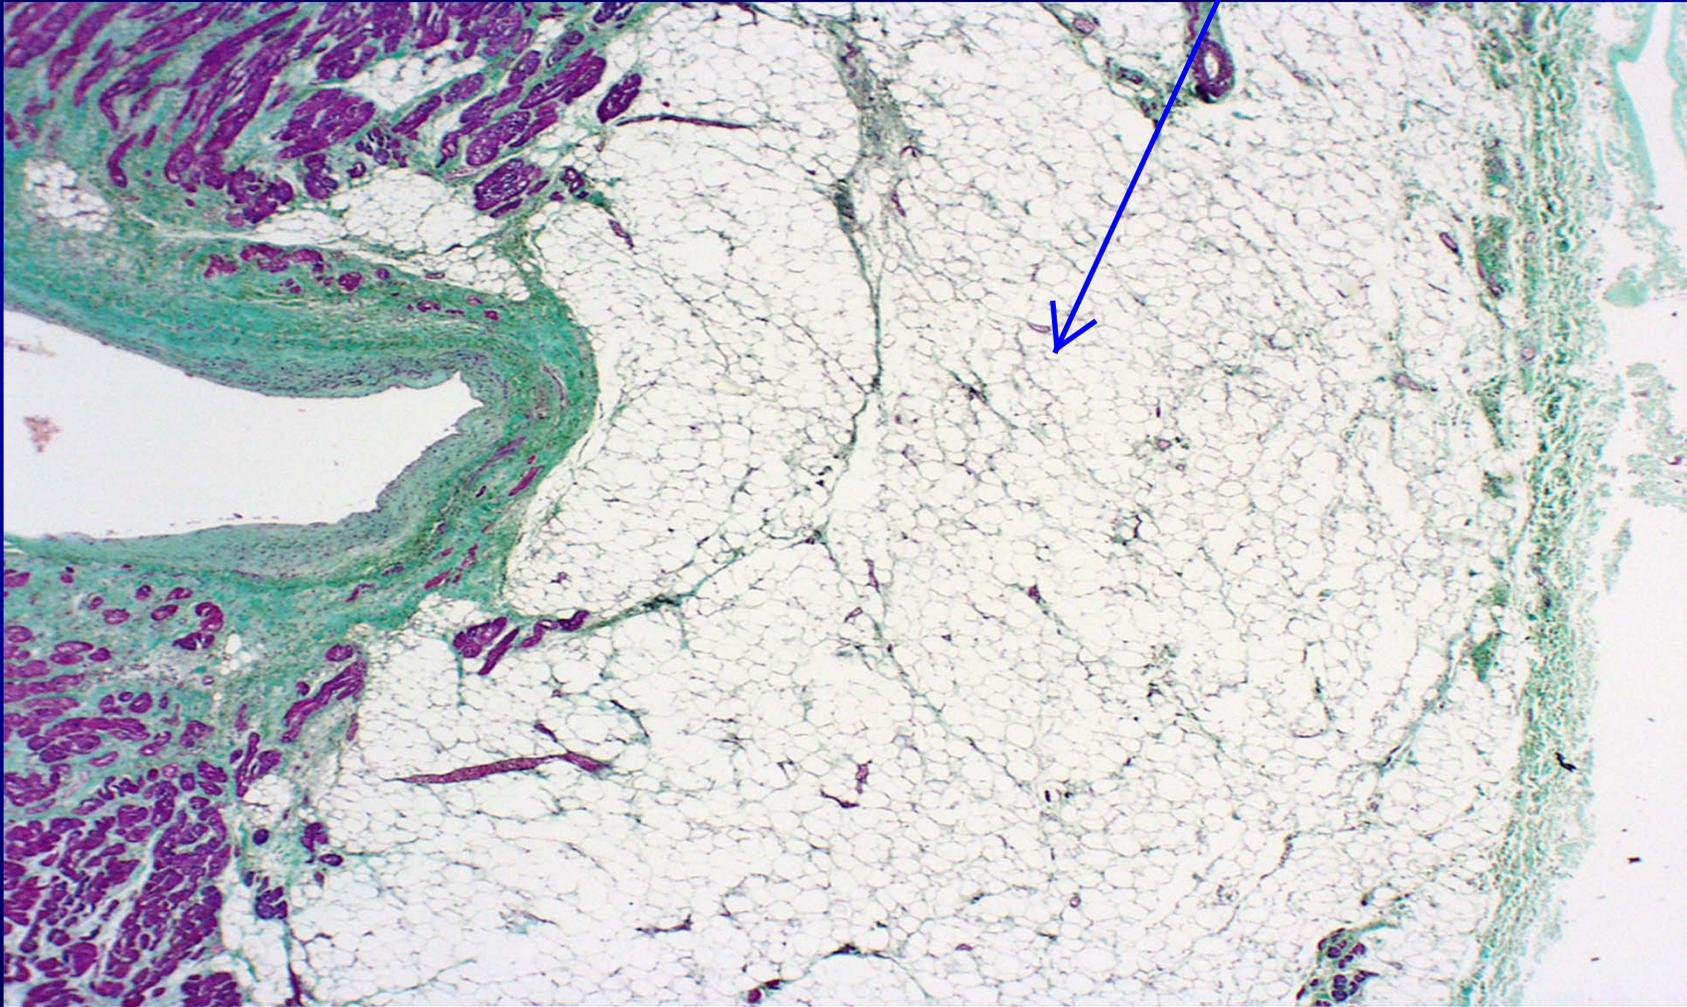

-Wall of right ventricle is replaced by fibrofatty tissue.

From gross picture:
-Starts at apex of RV and
can spread to LV as well.

ARVD

Transmural
replacement with
fatty tissue.

No treatment
other than
giving patient a
defibrillator to
keep them alive.
Some will go to
transplant.

Genetic Arrhythmias: No anatomic Cause

Ion channels

- Long QT Syndrome: Torsades, SCD in youth
 - 7 mutations identified. Some with associated syndromes
- Brugada Syndrome: \uparrow ST in right leads, RBBB
 - SCD in 20-30's often during rest/sleep
 - Cardiac sodium channel genes, *SCN5A* (LQT3), *KCNQ1* gene in forms associated with AF
- Catecholaminergic VT: Dom and recessive
 - Ca^{++} channel protein Ryanodine and Ca^{++} regulatory proteins.
 - Stress related trigger

For people who suffer SAD and don't have a cause, they take a blood sample and check for these disorders.

Commotio cordis

- **Sudden death following precordial impact**
- Impact location – directly over heart
- **Impact timing - T wave upstroke in window between 15-30 milliseconds prior to apex**
 - Potassium channels may play a role
- 2nd leading cause of SCD in athletes behind HCM
